Funder: Science Foundation Ireland
A novel Bézier spline-based geometry for printed monopole antennas is presented. Quadratic curves are used to describe the outline of the radiating element. The geometry is optimised by a genetic algorithm. A small number of control points are used to define the geometry, ensuring a small search space for the GA. The resulting antenna has an impedance bandwidth from 1.44 to 14.7 GHz.

Introduction: Geometries of recent UW B antennas are based on simple geometric elements, such as rectangles [1], circles [2] or ellipses [3], or a combination of these [4, 5]. This Letter proposes a geometry based on quadratic Bézier curves (splines). Splines are curves generated by quadratic interpolation between control points. The benefit of this technique is an inherently rounded shape of the radiating element. The design overcomes the geometrical constraints of a circular or elliptical disc and the difficulty of combining simple geometric elements. A genetic algorithm (GA)-based optimiser is used in the design process. GAs have been used for a variety of electromagnetic problems [6, 7], including the design of printed monopole antennas [8, 9].

**Fig. 1** Bézier spline outline and its control points (Pₙ), virtual control points (Pᵥₙ) and boundaries of the control points

Spline-based geometry: The outline of the radiating element is described by a quadratic Bézier spline. This spline curve is defined by eight control points P₀–P₇. Fig. 1 shows the outline curve and its control points. Point P₀ is fixed at (0,0), the point where the antenna is fed by a 50 Ω microstrip line. Points P₁–P₄ are defined by their x- and y-co-ordinates. Point P₄ is fixed at y=0 and can only be positioned along the x-axis. Points P₅–P₇ are derived from points P₁–P₄ by mirroring them along the x-axis. This creates a radiator with x-axis symmetry and provides quasi-omnidirectional radiation patterns in the H-plane (y-z plane). The low-frequency resonant modes yield omnidirectional properties irrespective of the symmetry, but the higher modes are travelling-wave modes [2] and their patterns are improved with symmetry. To achieve a closed curve in CST Microwave Studio, the curve is constructed in the following way. A ‘virtual’ control point Pᵥₙ is placed in the middle of each line between two control points. A quadratic Bézier curve is then generated from each adjacent pair of ‘virtual’ points with the real point between them. The tangent on each of these ‘virtual’ endpoints is the same for the two curves that meet there, so that a smooth transition between adjacent curve segments is ensured. The virtual points are marked by circles in Fig. 1.

The expression defining the set of quadratic Bézier curves Bₜ( ), n ∈ [0, 7] is given by:

$$B_t(t) = (1-t)^2 [P_{mm} + 2t(1-t) [P_{mm} + t^2 [P_{mm+1}]], t ∈ [0, 1], n ∈ [0, 7]$$

where Pᵥₙ is the ‘virtual’ control point before Pᵥₙ, and Pᵥₙ₊₁ is the ‘virtual’ control point after Pᵥₙ. For the case of n=7, Pᵥ₇ is P₇. The resulting curve does not pass through any of the endpoints Pᵥₙ.

**Genetic algorithm optimisation:** The position of the control points is optimised by a genetic algorithm. The problem is encoded in binary format. Single-point crossover and tournament selection are used. The mutation rate is 1%. The population size was set to 30 and evolved over 20 generations. Multiple objectives are used in the fitness function. The GA operates on points P₁–P₅ and the x-co-ordinate of point P₆ are encoded in a binary format. Altogether, these seven parameters are encoded to only 35 bits. This is a very small search space considering the complexity of the resulting geometry.

The design goal consists of two parts. The first is to optimise for a wide band between 0 and 20 GHz; this is weighted at 70%. The second goal is to reduce the lower edge frequency; this is weighted with 30%. The FDTD simulation software returns the S₁₁ as a list of 1000 frequency points. The fitness function is as follows:

$$fitness = 0.7BW + 0.3(1000 - f_{LE})$$

and f_{LE} = point of lower edge frequency, i.e. the smallest n where S₁₁(n) ≤ −10 dB. The final geometry optimised by the GA is shown in Fig. 2. It can be seen that the element curves away smoothly from the feed point. The maximal possible height is exploited as point P₆ is placed 35 mm away from the feed point. The computational time needed for the 600 evaluations amounts to four days on a single computer.

**Fig. 2** Optimised geometry of antenna

**Antenna geometry:** The antenna is printed on Rogers microwave laminate RO4350B of 0.762 mm thickness, εᵣ = 3.48 and tan δ = 0.0037. The substrate has a size of w₂ = 45 mm by l = 85 mm with the groundplane located on the rearide. The dimension of the groundplane is l₂ = 45 mm square. The antenna is fed by a microstrip feedline. The dimensions of the spline-based radiating element are l₁ = 33 mm by w₁ = 32 mm.
Results: The simulated and measured return losses are shown in Fig. 3. It can be seen that the measured return loss is greater than 10 dB from 1.44 to 14.7 GHz. This is an impedance bandwidth ratio of 10.2:1, which is very wide for a printed monopole. Measured radiation patterns are shown in Fig. 4. The H-plane patterns are omnidirectional up to about 8 GHz. The gain is 2.8 dBi at 2 GHz, 4.3 dBi at 6 GHz, 4.8 dBi at 10 GHz and 5.3 dBi at 14 GHz. The radiation efficiency at these frequencies is 91, 96, 92 and 89%, respectively. The antenna is proposed for multimode use in higher cellular, WLAN and UWB systems.

Conclusions: A novel Bézier spline-based technique for the design of printed monopole antennas has been presented. Only seven parameters are necessary to define the geometry; this also allows for a small 35 bit search space for the GA. It has been shown that this technique can give very wide bandwidths of 10.2:1.
