On Unit Sum Numbers of Rational Groups

B. Goldsmith, C. Meehan and S. Wallutis

Abstract.

The unit sum numbers of rational groups are investigated: the importance of the prime 2 being an automorphism of the rational group is discussed and other results are achieved by considering the number and distribution of rational primes which are, or are not, automorphisms of the group. Proof is given of the existence of rational groups with unit sum numbers greater than 2 but of finite value .

Unit sum numbers of Rational groups

§1 Introduction

The relationship between the groups of units of a unital associative ring and the ring itself has been studied in various forms over a long number of years. Prompted by a question of Fuchs [4], there has been special interest in the situation in which the ring is the full endomorphism ring of an abelian group, or more generally a module, and the group of units is then the corresponding automorphism group. Recall the definitions from [8]: an associative ring \mathbf{R} is said to have the *n-sum property* (for a positive integer n) if every element of \mathbf{R} can be written as the sum of exactly n units of \mathbf{R} . Clearly if this property holds for an integer n , then it also holds for any integer $k > n$, and so we can make the following definition of the unit sum number of a ring \mathbf{R} : $usn(\mathbf{R}) := \min\{n | \mathbf{R} \text{ has the } n\text{-sum property}\}$. If there is an element of \mathbf{R} which is not a sum of units we set the unit sum number to be ∞ while if every element of \mathbf{R} is a sum of units but \mathbf{R} does not have the n -sum property for any n , we set $usn(\mathbf{R}) = \omega$. The unit sum number of an abelian group or module is defined to be equal to that of its endomorphism ring. There is a considerable body of literature on this topic, often without using the terminology above. The principal works include [2, 3, 7, 8, 9, 12, 14, 15, 16] .

The focus of the current work is the problem of calculating unit sum numbers of rational groups i.e. subgroups of the additive group of rational numbers \mathbb{Q} . Although we have a

very concrete description of such groups in terms of types (see Fuchs[4, p.107]) it is not a simple problem to calculate the unit sum numbers: difficult number-theoretic issues arise and we shall indicate in Section 4, a relationship exists between our problem and some known approaches to additive number theory. Our principal result is that there exists a rational group G with finite unit sum number strictly greater than two.

Our terminology is standard and may be found in Fuchs [4, 5]; an exception is that we write maps on the right and we denote the set of rational primes by Π . Concepts from number theory may be found in Prachar[13] and from additive number theory in Nathanson[11]; in particular we shall have need of the function $\pi(x)$ defined, for a real number x , as the number of rational primes not exceeding x and also the function $\pi(x, k, l)$ defined, for a real number x and positive integers k, l with $(k, l)=1$, as the number of rational primes congruent to $l \pmod k$ and not exceeding x . We also adopt the standard practice, where necessary, of distinguishing a ring from a module by using bold face characters for the former.

§2 General considerations

The endomorphism ring of a rational group of type τ is easily described: it is the subring of \mathbb{Q} of type τ_0 , the reduced type of τ . Thus our consideration of unit sum numbers of rational groups reduces to the study of such rings.

The following two results reflect the importance of the prime number **2** in determining the unit sum numbers of rational groups .

Proposition 2.1 *Let G be a rational group. If 2 is not an automorphism of G then $\text{usn}(G)=\omega$.*

Proof: We need only consider $\mathbf{E}_{\mathbb{Z}}(G) = \mathbf{R}$, the subring of \mathbb{Q} containing \mathbb{Z} and with the reduced type of G . Consider an element $\frac{a}{b}$ of \mathbf{R} where a, b are positive integers . If b is even then $\left(\frac{a}{b}\right)\left(\frac{b}{2}\right) = \left(\frac{a}{2}\right)$ is an element of \mathbf{R} . Therefore a must be even or else $\frac{a-1}{2} \in \mathbb{Z}$

in which case $\left(\frac{a}{2}\right) - \left(\frac{a-1}{2}\right) = \left(\frac{1}{2}\right)$ must be an element of \mathbf{R} , contradicting 2 not being a unit of \mathbf{R} . Therefore if $\frac{a}{b}$ is a unit of \mathbf{R} , expressed in lowest form, then both a and b must be odd.

Let n be any even positive integer. Consider any sum of n units of \mathbf{R} ,

$$\frac{a_1}{b_1} + \frac{a_2}{b_2} + \dots + \frac{a_n}{b_n} = \frac{a_1 b_2 \dots b_n + a_2 b_1 b_3 \dots b_n + \dots + a_n b_1 \dots b_{n-1}}{b_1 \dots b_n},$$

where $\frac{a_i}{b_i}$ is a unit of \mathbf{R} expressed in lowest form for each $i \in 1, 2, \dots, n$. Observe that the denominator is a product of odd numbers and therefore odd and the numerator is an even sum of odd number products and therefore even. A sum of n units can never be a unit in this case. Therefore R has not got the n -sum property for any even integer n .

We know however that for any positive integer n a ring which has the n -sum property must also have the $(n + 1)$ -sum property. It follows that \mathbf{R} cannot have the n -sum property for any positive integer n . Every element of \mathbf{R} is a sum of units so we conclude that $\text{usn}(\mathbf{R}) = \text{usn}(G) = \omega$.

□

Proposition 2.2 *Let G be any rational group such that $\mathbf{E}_{\mathbb{Z}}(G) = \mathbb{Q}^{(2)}$, the rational group of type $(\infty, 0, 0, \dots)$.*

Then $\text{usn}(G) = \omega$.

Proof: We prove that for each positive integer n there is an integer, $1 + 2^2 + \dots + 2^n$, which cannot be expressed as a sum of n units of $\mathbb{Q}^{(2)}$. In $\mathbb{Q}^{(2)}$ each unit is of the form $\pm 2^a$ where a is an integer.

The proof is by induction. The induction statement is

$$1 + 2^2 + \dots + 2^{2n} \neq \sum_{\substack{i=1 \\ a_i \in \mathbb{Z}}}^n \pm 2^{a_i} \quad , \text{for all } n \in \mathbb{Z}^+. \quad (*)$$

The statement is true for $n = 1$ since $1 + 2^{2(1)} = 5$ and 5 is not a unit. We assume the statement is true for all positive integers $n < m$. Now seeking a contradiction let,

$$1 + 2^2 + \dots + 2^{2m} = \sum_{\substack{i=1 \\ a_i \in \mathbb{Z}}}^m \pm 2^{a_i}. \quad (1)$$

for some fixed set of integers a_1, \dots, a_m . The left hand side of this equation is odd so

$\sum_{a_i < 2} \pm 2^{a_i} \neq 0$ and is an odd integer. We rewrite the equation with renumbering and

rearrange as

$$2^2 + \dots + 2^{2m} = \left(\sum_{\substack{i=1 \\ a_i < 2}}^l \pm 2^{a_i} - 1 \right) + \sum_{\substack{i=l+1 \\ a_i \geq 2}}^m \pm 2^{a_i}, \quad \text{some } 1 < l \leq m. \quad (2)$$

We claim that the term $\left(\sum_{\substack{i=1 \\ a_i < 2}}^l \pm 2^{a_i} - 1 \right)$ can be written as a sum of less than l units in $\mathbb{Q}^{(2)}$.

Observe from the equation that 4 divides $\left(\sum_{\substack{i=1 \\ a_i < 2}}^l \pm 2^{a_i} - 1 \right)$. So writing $\left(\sum_{\substack{i=1 \\ a_i < 2}}^l \pm 2^{a_i} - 1 \right) = 4l'$

for some $l' \in \mathbb{Z}$, we note that this expresses $\left(\sum_{\substack{i=1 \\ a_i < 2}}^l \pm 2^{a_i} - 1 \right)$ as a sum of $|l'|$ units for

$l' \neq 0$.

To prove the claim we must show $|l'| < l$.

If $l' = 0$ then $|l'| < l$.

If $l' \neq 0$: Since $2^{a_i} \leq 2$ for all $a_i < 2$ it is clear that

$\left| \left(\sum_{\substack{i=1 \\ a_i < 2}}^l \pm 2^{a_i} - 1 \right) \right| = |4l'| \leq 2l + 1$. Since $l' \neq 0$ then we can write $|2l'| + 1 < 2l + 1$ which

gives us $|l'| < l$.

The claim is proved.

Returning to equation (2), if $\left(\sum_{\substack{i=1 \\ a_i < 2}}^l \pm 2^{a_i} - 1 \right)$ can be expressed as zero or a sum of less than l units then $2^2 + \dots + 2^{2m}$ can be expressed as a sum of less than m units. Then we may write,

$$2^2 + \dots + 2^{2m} = \sum_{\substack{j=1 \\ b_j \in \mathbb{Z}}}^{m'} \pm 2^{b_j} \quad , \text{for some } m' < m.$$

Dividing this equation by 4 we get,

$$1 + \dots + 2^{2(m-1)} = \sum_{\substack{j=1 \\ b_j \in \mathbb{Z}}}^{m'} \pm 2^{b_j-2}.$$

This contradicts the induction statement (*) for $n = m - 1$ and so the assumption (1) is false and the proof now follows by induction. Therefore $\text{usn}(G) = \text{usn}(\mathbb{Q}^{(2)}) = \omega$. \square

The next two lemmas enable us to make some simplifications in our approach.

Lemma 2.3 *Let G be a rational group with $\mathbf{E}_{\mathbb{Z}}(G) = \mathbf{R}$. If $\frac{1}{2} \in \mathbf{R}$ then G has the n -sum property if and only if every positive integer is a sum of exactly n units of \mathbf{R} .*

Proof: Clearly, if \mathbf{R} has the n -sum property for some positive integer n then every positive integer is a sum of n units of \mathbf{R} .

Conversely, suppose every positive integer is expressible as a sum of n units of \mathbf{R} . Then every negative integer must also be expressible as a sum of n units of \mathbf{R} and since $0 = 1 - \sum_{i=1}^{n-2} \frac{1}{2^i} - \frac{1}{2^{n-2}}$, all integers are sums of n units.

Consider an arbitrary non-integer element of \mathbf{R} , $\frac{a}{b}$, expressed in lowest form.

If $a = 1$, then $\left(\frac{a}{b}\right)$ is a unit. Since products of units are units and 1 is a sum of n units then $\left(\frac{a}{b}\right)(1)$ is also.

If $b = 1$, then $\frac{a}{b} = a$, an integer, and so is a sum of n units.

In any remaining case a and b must be relatively prime so there exist integers k, l such that $ka + lb = 1$. Now $(k\left(\frac{a}{b}\right) + l)$ is an element of R and $(k\left(\frac{a}{b}\right) + l)(b) = 1$. Therefore b is a unit of \mathbf{R} and so also is $\frac{1}{b}$. Since a , as an integer, is a sum of n units then $\frac{1}{b}(a)$ is also. \square

Lemma 2.4 *Let G_1, G_2 be rational groups such that $\mathbf{E}_{\mathbb{Z}}(G_1) \leq \mathbf{E}_{\mathbb{Z}}(G_2)$, then $\text{usn}(G_1) \geq \text{usn}(G_2)$.*

Proof: Since $\mathbf{E}_{\mathbb{Z}}(G_1) \leq \mathbf{E}_{\mathbb{Z}}(G_2)$ then every unit of $\mathbf{E}_{\mathbb{Z}}(G_1)$ is also a unit of $\mathbf{E}_{\mathbb{Z}}(G_2)$. So if a positive integer z is a sum of n units in $\mathbf{E}_{\mathbb{Z}}(G_1)$ then the same is true for z as an element of $\mathbf{E}_{\mathbb{Z}}(G_2)$. Therefore by Lemma 2.3 $\text{usn}(\mathbf{E}_{\mathbb{Z}}(G_2)) \leq \text{usn}(\mathbf{E}_{\mathbb{Z}}(G_1))$ and so $\text{usn}(G_2) \leq \text{usn}(G_1)$. \square

§3 Unit sum numbers for various rational groups

Given the description of the endomorphism ring of a rational group G in terms of a reduced type, it is natural to consider the set $X_G := \{p \in \Pi \mid \frac{1}{p} \notin \mathbf{E}_{\mathbb{Z}}(G)\}$, where Π denotes the set of rational primes.

Theorem 3.1 *Let G be a rational group with $2 \in \text{Aut}(G)$. If X_G is a finite set then $\text{usn}(G) = 2$.*

Proof: Let $\mathbf{R} = \mathbf{E}_{\mathbb{Z}}(G)$ and enumerate $X_G = \{q_i \mid i = 1, \dots, k\}$. By Lemma 2.3, we need only prove all positive integers are sums of two units of \mathbf{R} . Clearly if 2 is a unit of

\mathbf{R} then every unit of \mathbf{R} is a sum of two units. Now by definition of X_G we know that for all $p \in \Pi \setminus X_G$, p is a unit of \mathbf{R} and so any products of primes not in X_G are units of \mathbf{R} also. Let $z = \left(\prod_{\substack{q_i \in X_G; i=1, \dots, k \\ m_i \in \mathbb{N}}} q_i^{m_i} \right) \left(\prod_{\substack{p_j \in \Pi \setminus X_G \\ n_j \in \mathbb{N}}} p_j^{n_j} \right)$ be an arbitrary positive integer which is not a unit in \mathbf{R} , i.e. some $q_i \in X_G$ divides z .

Since $\left(\prod_{\substack{p_j \in \Pi \setminus X_G \\ n_j \in \mathbb{N}}} p_j^{n_j} \right)$ is a unit we need only show that $z' = \left(\prod_{\substack{q_i \in X_G; i=1, \dots, k \\ m_i \in \mathbb{N}}} q_i^{m_i} \right)$ is a sum of two units of \mathbf{R} . If every q_i in X_G divides z' then $(z' - 1)$ is relatively prime to all $q_i \in X_G$ and therefore a unit, in which case $z' = (z' - 1) + 1$ is a sum of two units for z' .

If some q_i in X_G do not divide z' then $(z' \pm \prod_{\substack{q_i \in X_G \\ q_i \nmid z'}} q_i)$ is a unit since no prime in X_G can divide it. In this way, $z' = \frac{1}{2}(z' + \prod_{\substack{q_i \in X_G \\ q_i \nmid z'}} q_i) + \frac{1}{2}(z' - \prod_{\substack{q_i \in X_G \\ q_i \nmid z'}} q_i)$ expresses z' as a sum of two units and the result follows. \square

We can extend Theorem 3.1 to some cases where X_G is not finite; our next result shows some similarity to an example of Opdenhövel [12].

Proposition 3.2 *Let G be a rational group with $\mathbf{E}_{\mathbb{Z}}(G) = \mathbf{R}$ where $2 \notin X_G$. If for any $x \in \mathbb{Z}^+$ such that $(x, p) = 1$ for all $p \in \Pi \setminus X_G$ there is some $x < q \in \Pi$ so that $q' \notin X_G$ for all $q' \in \Pi$ with $q \leq q' < q^{\pi(q)}$, then $\text{usn}(G) = 2$.*

Proof: It suffices to show that products of elements of X_G are sums of two units of \mathbf{R} . Let x be such a product. If there is some $q \in \Pi$ with $x < q$ so that $q' \notin X_G$ for all $q' \in \Pi$ with $q \leq q' < q^{\pi(q)}$ then we claim that x is a sum of two units as follows;

$$x = \frac{1}{2} \left(x + \prod_{\substack{q_i \in X_G \\ q_i \nmid x; q_i < q}} q_i \right) + \frac{1}{2} \left(x - \prod_{\substack{q_i \in X_G \\ q_i \nmid x; q_i < q}} q_i \right).$$

To prove this claim we need to show that $(x + \prod_{\substack{q_i \in X_G \\ q_i \nmid x; q_i < q}} q_i)$ is a unit of \mathbf{R} . Let $p \in \Pi$ be such that p divides $(x + \prod_{\substack{q_i \in X_G \\ q_i \nmid x; q_i < q}} q_i)$.

If $p < q$; since all primes in X_G less than q are accounted for by the prime factors of x and $(\prod_{\substack{q_i \in X_G \\ q_i \nmid x; q_i < q}} q_i)$, then by construction p cannot divide both x and $(\prod_{\substack{q_i \in X_G \\ q_i \nmid x; q_i < q}} q_i)$ so $p \notin X_G$.

If $q \leq p < q^{\pi(q)}$ then $p \notin X_G$ by the condition that $q' \notin X_G$ for all $q' \in \Pi$ with $q \leq q' < q^{\pi(q)}$.

Now we consider $q^{\pi(q)} \leq p$. Note that by construction, $x < q$ and that $q > 3$ so $q^{\pi(q)} > q^{\pi(q)-1} + q$. Also notice that $|\{q_i \in X_G; q_i < q\}| < \pi(q) - 1$, i.e. $2 \notin X_G$,

$$\text{so } \left(\prod_{\substack{q_i \in X_G \\ q_i \nmid x; q_i < q}} q_i \right) < \left(\prod_{\substack{q_i \in X_G \\ q_i < q}} q \right) < q^{\pi(q)-1}.$$

$$\text{Therefore } \left| \left(x + \prod_{\substack{q_i \in X_G \\ q_i \nmid x; q_i < q}} q_i \right) \right| < q^{\pi(q)-1} + q < q^{\pi(q)}.$$

So $p \geq q^{\pi(q)}$ cannot divide $\left(x + \prod_{\substack{q_i \in X_G \\ q_i \nmid x; q_i < q}} q_i \right)$ since it is too big. Therefore the integer

$\left(x + \prod_{\substack{q_i \in X_G \\ q_i \nmid x; q_i < q}} q_i \right)$ must be a product of primes not contained in X_G and therefore a unit of \mathbf{R} .

R. By a similar argument $\left(x - \prod_{\substack{q_i \in X_G \\ q_i \nmid x; q_i < q}} q_i \right)$ is a unit of \mathbf{R} also. □

Example 3.3 Denote by $\tau^1[n]$ ($n \in \mathbb{Z}^+$) the index of the least prime greater than $p_n^{\pi(p_n)}$ (i.e. $p_{\tau^1[n]}$ is the least prime greater than $p_n^{\pi(p_n)}$) and set $\tau^1[\tau^{(m-1)}[n]] = \tau^m[n]$, for all integers $m > 1$.

Let \mathbf{R} be the subring of \mathbb{Q} with $\text{type}(\mathbf{R}) = (k_{p_i})$ where

$$k_{p_i} = \begin{cases} \infty & \text{for } i = 1 \\ 0 & \text{for } 1 < i \leq \tau^1[2] \\ \infty & \text{for } \tau^1[2] < i \leq \tau^2[2] \\ \dots & \dots \\ 0 & \text{for } \tau^j[2] < i \leq \tau^{j+1}[2], j(> 1) \text{ even} \\ \infty & \text{for } \tau^j[2] < i \leq \tau^{j+1}[2], j(> 1) \text{ odd} \end{cases}$$

By Proposition 3.2, any rational group, G , with $\mathbf{E}_{\mathbb{Z}}(G) > \mathbf{R}$ has unit sum number 2.

Next, rational groups are investigated which have only two symbols ∞ within their reduced type or in other words where $|\Pi \setminus X_G| = 2$. Because of the importance of the prime 2, as illustrated in Proposition 2.1, we are, in fact, considering groups of the type $(\infty, r_2, r_3, \dots)$ where only a single r_i is ∞ , the rest being finite. We begin with a technical

lemma.

Lemma 3.4 *Let $a, b, c, d \in \mathbb{Z} \setminus \{0\}$ and let $\frac{a}{b}, \frac{c}{d}$ be rational numbers expressed in lowest form. If $(\frac{a}{b} + \frac{c}{d})$ is an integer then $b = \pm d$.*

Proof: Straightforward. □

Corollary 3.5 *Let $k, l, m, n \in \mathbb{Z}$. Let z be an integer and let $p \neq 2$ be a rational prime such that $z = \pm(2^k p^l \pm 2^m p^n)$. If $k < 0$ (or $m < 0$) then $k = m$. If $l < 0$ (or $n < 0$) then $l = n$.*

Proof This follows directly from Lemma 3.4 □

The following proposition provides a useful simplification in discussing the 2–sum property for all rational groups with only two symbols infinity in their reduced type, one of which corresponds to the rational prime 2.

Lemma 3.6 *Let $p \in \Pi \setminus \{2\}$ and let G be a rational group with $\mathbf{E}_{\mathbb{Z}}(G) = \mathbf{R}$, where \mathbf{R} is the subring of \mathbb{Q} generated by $\frac{1}{2}$ and $\frac{1}{p}$. Then $\text{usn}(G) = 2$ if and only if every positive integer z with $(z, 2) = 1 = (z, p)$ can be expressed in one of the following forms:*

$$(1) \quad z = \pm(2^k \pm p^l) \quad \text{for some } k > 0, l > 0.$$

$$(2) \quad z = 2^k p^l \pm 1 \quad \text{for some } k > 0, l \geq 0.$$

$$(3) \quad z = \frac{1}{p^l}(2^k \pm 1) \quad \text{for some } k > 0, l > 0.$$

$$(4) \quad z = \frac{1}{2^k}(p^l \pm 1) \quad \text{for some } k > 0, l > 0.$$

where $k, l \in \mathbb{Z}$.

Proof: In the first direction we assume that $\text{usn}(G) = 2$ and so $\text{usn}(\mathbf{R}) = 2$. Every unit of \mathbf{R} is of the form $\pm 2^a p^b$ where $a, b \in \mathbb{Z}$. Let z be a positive integer greater than 1 and relatively prime to both 2 and p . Let $z = \pm(2^a p^b \pm 2^c p^d)$ be a two unit sum for z , where $a, b, c, d \in \mathbb{Z}$. Notice that a, b, c, d cannot all be less than or equal to zero since z cannot

take the values $\pm 1, \pm 2$, or 0.

By Corollary 3.5 if $a < 0$ then $c = a$ and since z is relatively prime to 2 then if either a or c is greater than 0 then the other must be zero, i.e. if $a > 0$ then $c = 0$. Similarly if $b < 0$ then $d = b$ and since z is relatively prime to p then if either b or d is greater than 0 then the other must be zero, i.e. if $b > 0$ then $d = 0$. In light of this we consider the possible two unit sums for z .

If $a > 0$ (forcing $c = 0$) and $d > 0$ (forcing $c = 0$) then $z = \pm(2^a \pm p^d)$. This is of form **(1)**. Similarly form **(1)** occurs for $c > 0$ and $b > 0$.

If $a > 0$ (forcing $c = 0$) and $b > 0$ (forcing $d = 0$) then $z = 2^a p^b \pm 1$. Note that only one \pm sign occurs in this equation and it must accompany the 1, otherwise a negative integer would result. This equation is of form **(2)**. Similarly form **(2)** occurs for $c > 0$ and $d > 0$.

If $a = c < 0$ then $b > 0$ and $d = 0$, or $b = 0$ and $d > 0$ resulting in $z = \frac{1}{2^{-a}}(p^b \pm 1)$ or $z = \frac{1}{2^{-a}}(p^d \pm 1)$. Notice there is only one \pm sign in each equation and it must precede the 1 otherwise a negative integer would result. These equations are of form **(4)**.

If $b = d < 0$ then $a > 0$ and $c = 0$, or $a = 0$ and $c > 0$ resulting in $z = \frac{1}{p^{-b}}(2^a \pm 1)$ or $z = \frac{1}{p^{-b}}(2^c \pm 1)$. Again the only \pm sign accompanies the 1 or a negative integer results. These equations are of form **(3)**.

If $b = d = 0$ then $a > 0$ and $c = 0$, or $a = 0$ and $c > 0$ resulting in $z = 2^a \pm 1$ or $z = 2^c \pm 1$. These equations are of form **(2)**.

We have covered all possible cases.

In the other direction let x be a positive integer. We can write $x = 2^a p^b(z)$ with $a, b \in \mathbb{Z}$ where $(z, 2) = 1 = (z, p)$ or $z = 1$. If $z (\neq 1)$ can be expressed in one of the forms **(1),(2),(3)** or **(4)** then, since $1 = \frac{1}{2} + \frac{1}{2}$, every positive integer can be expressed as $\text{unit}(\text{unit} + \text{unit})$. Then by Lemma 2.3 $\text{usn}(G) = 2$. \square

It is convenient for our purposes to consider the primes modulo 24. Excluding 2 and 3 the primes fall into eight classes modulo 24, these being 1, 5, 7, 11, 13, 17, 19 and 23 mod 24. By Dirichlet's famous theorem (see Prachar[13, **IV**, Theorem 4.3]) for primes in an arithmetic progression, we know that in each of these classes there is an infinite number of primes. Let P^* denote the set of primes $\{p \in \Pi \mid p \equiv 1, 5, 11, 13, 19 \text{ or } 23 \pmod{24}\}$.

Proposition 3.7 Let $P_{25}^* = P^* \setminus \{5, 13, 23, 29, 101\}$ and $p \in P_{25}^*$. Let \mathbf{R} be the subring of \mathbb{Q} generated by $\frac{1}{2}$ and $\frac{1}{p}$. Then $\text{usn}(\mathbf{R}) > 2$.

Proof: We will show that 25 cannot be expressed as a sum of two units in \mathbf{R} and therefore $\text{usn}(\mathbf{R}) > 2$. Since $(25, p) = 1$ for all $p \in P_{25}^*$, and $(25, 2) = 1$, then by Proposition 3.6 if 25 can be expressed as a sum of two units of \mathbf{R} it must be expressible in one of the forms (1), (2), (3) or (4).

Form (1): We tabulate modulo 24 values of $\pm 2^k \pm p^l$ for $k, l > 0$ and for all possible values of p in P^* .

		$\pm p^l \text{ mod } 24$					
		1	5	11	13	19	23
$\pm 2^k \text{ mod } 24$	+						
	2	3	7	13	15	21	1
	4	5	9	15	17	23	3
	8	9	13	19	21	3	7
	16	17	21	3	5	11	15
	-4	21	1	7	9	15	19
	-2	23	3	9	11	17	21

Table: $\pm 2^k \pm p^l \text{ mod } 24$; $k, l > 0, p \in P^*$.

On this table 1 mod 24 occurs only for $\pm 2^k \equiv 2$ or $-4 \text{ mod } 24$, which correspond to $\pm 2^k = 2$ or -4 . However $25 = 2 \pm p^l$ implies that $p = 23$, which is not contained in P_{25}^* ; and $25 = -4 \pm p^l$ implies $p = 29$, which is not contained in P_{25}^* . Therefore 25 does not occur in \mathbf{R} as form (1).

Form (2): This time we tabulate values of $2^k p^l$ modulo 24 for $k > 0, l \geq 0$ and for all values of p in P^* .

		$p^l \bmod 24$					
\times		1	5	11	13	19	23
	2	2	10	22	2	14	22
	4	4	20	20	4	4	20
$\pm 2^k \bmod 24$	8	8	16	16	8	8	16
	16	16	8	8	16	16	8

Table: $2^k p^l \bmod 24$; $k > 0$, $l \geq 0$, $p \in P^*$.

From this table we deduce that $2^k p^l \pm 1$ with $k > 0$ and $l \geq 0$ can only be congruent to 1 mod 24 for $k = 1$ (i.e. see values resulting in 0 or 2 in the table above). However $25 = 2p^l \pm 1$ implies $p = 13$ which is not contained in P_{25}^* . Therefore 25 does not occur in \mathbf{R} as form (2).

Form (3): The set of congruences modulo 24 for $25p^l$ with $l > 0$ and $p \in P^*$ is $\{1, 5, 11, 13, 19, 23\}$. The set of congruences modulo 24 for $2^k \pm 1$ with $k > 0$ is $\{1, 3, 5, 7, 9, 15, 17\}$. Values common to both sets are 1 and 5 mod 24; these correspond to $k = 1$ and $k = 2$. Since $25 > 2^k \pm 1$ for $k = 1$ or 2, then 25 cannot be expressed as form (3) in \mathbf{R} .

Form (4): The set of congruences modulo 24 for $25(2^k)$ with $k > 0$ is $\{2, 4, 8, 16\}$. The set of congruences modulo 24 for $p^l \pm 1$ with $l > 0$ and $p \in P^*$ is $\{0, 2, 4, 6, 10, 12, 14, 18, 20, 22\}$. Only the congruences 2 and 4 mod 24 occur in both sets. These correspond to $k = 1$ or 2. For $k = 1$ we get $2(25) = p^l \pm 1$ giving $p^l = 49$ or 51 both of which are impossible for $p \in P^*$. For $k = 2$ we get $4(25) = p^l \pm 1$ giving $p^l = 99$ or 101, neither of which is possible for $p \in P_{25}^*$. Therefore 25 cannot be expressed in form (4) in R . \square

Proposition 3.8 *Let $P_{73}^* = P^* \setminus \{37, 71, 293\}$ and $p \in P_{73}^*$. If \mathbf{R} is the subring of \mathbb{Q} generated by $\frac{1}{2}$ and $\frac{1}{p}$, then $\text{usn}(\mathbf{R}) > 2$.*

Proof: We will show that 73 cannot be expressed as a sum of two units in \mathbf{R} . The proof follows Proposition 3.7 exactly, so we summarise just one form:

Form (1): Let $73 = 2 \pm p^l$ with $l > 0$ and $p \in P^*$. This implies $p = 71$ which is not contained in P_{73}^* .

Let $73 = -4 \pm p^l$ with $l > 0$ and $p \in P^*$. This implies that $77 = p^l$ which is impossible

for $p \in P^*$. Therefore 73 cannot be of form (1) in \mathbf{R} . \square

Corollary 3.9 *Let $p \in P^*$. If \mathbf{R} is the subring of \mathbb{Q} generated by $\frac{1}{2}$ and $\frac{1}{p}$ and if G is a rational group such that $\mathbf{E}_{\mathbb{Z}} = \mathbf{R}$, then $\text{usn}(G) > 2$.*

Proof: Recall from Propositions 3.7 and 3.8 that $P_{25}^* = P^* \setminus \{5, 13, 23, 29, 101\}$ and $P_{73}^* = P^* \setminus \{37, 71, 293\}$. Therefore $P^* = P_{25}^* \cup P_{73}^*$. The proof then follows directly from these two propositions. \square

Using similar arithmetic arguments we can establish the following:

Theorem 3.10 *Let $p \in \Pi \setminus \{2\}$. Let G be a rational group such that $\mathbf{E}_{\mathbb{Z}}(G)$ is the subring of \mathbb{Q} generated by $\frac{1}{2}$ and $\frac{1}{p}$. Then $\text{usn}(G) > 2$.*

Proof: Full details may be found in Meehan [10, III]. \square

If \mathcal{P} is a proper subset of Π containing 2 and at least one other prime, then we have the following analogue of the reduction Lemma 3.6.

Proposition 3.11 *Let $\{2\} \subsetneq \mathcal{P} \subsetneq \Pi$. Let G be a rational group such that $\mathbf{E}_{\mathbb{Z}}(G)$ is the subring of \mathbb{Q} generated by $\{\frac{1}{p} \mid p \in \mathcal{P}\}$. Then $\text{usn}(G) = 2$ if and only if every positive integer z with $(z, p) = 1$ for all $p \in \mathcal{P}$ can be expressed in one of the following forms:*

$$(a) \quad z = \frac{1}{2^m B} (C \pm D)$$

$$(b) \quad z = \pm \frac{1}{B} (2^m C \pm D)$$

where $m \in \mathbb{Z}^+$ and B, C, D are products of elements of $\mathcal{P} \setminus \{2\}$ such that $(B, C) = 1 = (C, D) = (B, D)$.

Proof: The proof is similar to that of Lemma 3.6. For full details see Meehan [10]. \square

Corollary 3.12 *Let G be a rational group such that $\mathbf{E}_{\mathbb{Z}}(G)$ is the subring of \mathbb{Q} generated by $\{\frac{1}{2}\} \cup \{\frac{1}{p} \mid p \in \Pi, p \equiv 1 \pmod{24}\}$. Then $\text{usn}(G) > 2$.*

Proof: Consider the set $\mathcal{P} = \{2\} \cup \{p \in \Pi \mid p \equiv 1 \pmod{24}\}$ and let $z = 11$. Then z is not of the form (a) since:

$$(C \pm D) \equiv 0 \text{ or } 2 \pmod{24} \quad \text{and}$$

$$2^m \cdot 11B \equiv 22, 20, 16 \text{ or } 8 \pmod{24}.$$

Moreover, z is not of form (b) either, since:

$$11B \equiv 11 \pmod{24} \quad \text{and}$$

$$\pm(2^m C \pm D) \equiv \pm 1, \pm 3, \pm 5, \pm 7, \pm 9, \pm 15 \text{ or } \pm 17 \pmod{24}.$$

Therefore by Proposition 3.11 $\text{usn}(\mathbf{R}) \neq 2$. □

By Dirichlet's Theorem (see [13, IV, Theorem 4.3]), the set $\{p \in \Pi \mid p \equiv 1 \pmod{24}\}$ is infinite and co-infinite and so the group G in Corollary 3.12 is an example of a rational group having endomorphism ring \mathbf{R} with $\Pi \setminus X_G$ infinite but $\text{usn}(\mathbf{R}) \neq 2$. In the next section we shall see that $\text{usn}(G)$ is finite.

§4 A number theoretical approach

A different line of approach is followed now adapting some results from additive number theory to get some interesting outcomes. We begin by recalling some fundamental notions and results; further background material may be found in Nathanson [11].

Definitions 4.1 *Let A be a set of integers, $x \in \mathbb{Z}$, and $h \in \mathbb{N}$.*

- (i) *The Counting Function of the set A , defined for $x \in \mathbb{Z}$, is the number of positive elements of A not exceeding x , written $A(x)$,*

$$A(x) = \sum_{\substack{a \in A \\ 1 \leq a \leq x}} 1.$$

- (ii) *The Shnirel'man Density of the set A , denoted $\sigma(A)$, is*

$$\sigma(A) = \inf_{n=1,2,\dots} \left(\frac{A(n)}{n} \right)$$

- (iii) *The set A is a basis of order h if every non-negative integer can be expressed as a sum of exactly h elements of A .*

We include here some results which will be used later.

Lemma 4.2 *Let x be a positive integer greater than 2. Let $r(N)$ denote the number of representations of the integer N as the sum of two primes.*

Then

$$(i) \sum_{N \leq x} r(N) > c_1 \frac{x^2}{(\ln x)^2}, \quad \text{for some positive constant } c_1 .$$

$$(ii) \sum_{N \leq x} (r(N))^2 \leq c_2 \frac{x^3}{(\ln x)^4}, \quad \text{for some positive constant } c_2 .$$

Proof: See Nathanson[11, Lemmas 7.6/7.7]. □

Lemma 4.3 *Let A and B be sets of integers such that $0 \in A$, $0 \in B$.*

(i) *If $n \in \mathbb{N}$ and $A(n) + B(n) \geq n$, then $n \in A + B$.*

(ii) *If $\sigma(A) + \sigma(B) \geq 1$, then $n \in A + B$ for each $n \in \mathbb{N}$.*

(iii) *If $\sigma(A) > \frac{1}{2}$ then A is a basis of order 2.*

Proof: For (i) and (ii) see Nathanson [11, Lemmas 7.3/7.4]; (iii) follows immediately from (ii) taking $A = B$. □

Theorem 4.4 (*Shnirel'man*) *Let A and B be sets of integers such that $0 \in A$, $0 \in B$.*

Let $\sigma(A) = \alpha$ and $\sigma(B) = \beta$. Then

$$\sigma(A + B) \geq \alpha + \beta - \alpha\beta.$$

Proof: See Nathanson [11, Theorem 7.5]. □

Theorem 4.5 *Let $h \geq 1$, and let A_1, \dots, A_h be sets of integers such that $0 \in A_i$ for $i \in 1, \dots, h$. Then*

$$1 - \sigma(A_1 + \dots + A_h) \leq \prod_{i=1}^h (1 - \sigma(A_i)).$$

Proof: The proof is by induction on h . Let $\sigma(A_i) = \alpha_i$ for $i = 1, \dots, h$. For $h = 1$ there is nothing to prove. For $h = 2$, the inequality follows from Theorem 4.4.

Let $k \geq 3$, and assume the theorem holds for all $h < k$. Let $B = A_1 + \dots + A_{k-1}$. It follows from the induction hypothesis that

$$1 - \sigma(B) = 1 - \sigma(A_1 + \dots + A_{k-1}) \leq \prod_{i=1}^{k-1} (1 - \sigma(A_i)) \quad ,$$

and so

$$\begin{aligned} 1 - \sigma(A_1 + \dots + A_k) &= 1 - \sigma(B + A_k) \\ &\leq (1 - \sigma(B))(1 - \sigma(A_k)) \quad (\text{by Theorem 4.4}) \\ &\leq (1 - \sigma(A_k)) \prod_{i=1}^{k-1} (1 - \sigma(A_i)) \\ &= \prod_{i=1}^k (1 - \sigma(A_i)). \end{aligned}$$

This completes the proof. □

The following theorem is fundamental to our line of approach.

Theorem 4.6 (*Shnirel'man*)

Let A be a set of integers such that $0 \in A$ and $\sigma(A) = \alpha > 0$.

Then A is a basis of finite order.

Further, A is a basis of finite order at most $h = 2l$, $h, l \in \mathbb{N}$ where l is defined by

$$0 \leq (1 - \alpha)^l \leq \frac{1}{2}.$$

Proof: Let $\sigma(A) = \alpha > 0$. Then $0 \leq 1 - \alpha < 1$, and so

$$0 \leq (1 - \alpha)^l \leq \frac{1}{2} \quad , \text{ for some integer } l \geq 1.$$

By Theorem 4.5,

$$1 - \sigma(lA) \leq (1 - \sigma(A))^l = (1 - \alpha)^l \leq \frac{1}{2},$$

and so $\sigma(lA) \geq \frac{1}{2}$. Let $h = 2l$. It follows from Corollary ?? that the set lA is a basis of order $2l = h$. This completes the proof. □

Theorem 4.7 (*Shnirel'man-Goldbach*)

The set $A = \{0, 1\} \cup \{p + q \mid p, q \in \Pi\}$ has positive Shnirel'man density.

Proof: See [11, Theorem 7.8]. □

Lemma 4.8 *Let \mathcal{S} be a subset of Π which contains a positive proportion of Π , in the sense that $\mathcal{S}(x) > \theta\pi(x)$ for some $\theta(> 0) \in \mathbb{R}$ and for all sufficiently large $x \in \mathbb{Z}$.*

Then the set $\mathcal{S} \cup \{0, 1\}$ is a basis of finite order.

Proof: We show that the set $\mathcal{A} = \{0, 1\} \cup \{p + q; p, q \in \mathcal{S}\}$ has positive Shnirel'man density. For any positive integer N let $r(N)$ denote the number of representations of N as a sum of two primes and let $r_{\mathcal{S}}(N)$ denote the number of representations of N as a sum of two primes belonging to \mathcal{S} . Then, for all sufficiently large $x \in \mathbb{Z}$,

$$\sum_{N \leq x} r_{\mathcal{S}}(N) \geq \left(\mathcal{S}\left(\frac{x}{2}\right)\right)^2 \geq (\theta\pi\left(\frac{x}{2}\right))^2,$$

and by the Prime Number Theorem (see [13, **III** Theorem 2.4])

$$(\theta\pi\left(\frac{x}{2}\right))^2 \geq c_1 \left(\frac{x}{\log \frac{x}{2}}\right)^2, \quad \text{for some positive constant } c_1.$$

Also by Lemma 4.2 (ii),

$$\sum_{N \leq x} (r_{\mathcal{S}}(N))^2 \leq c_2 \frac{x^3}{(\log x)^4}, \quad \text{for some positive constant } c_2.$$

Now by the Cauchy-Schwarz inequality (see [14, Lemma 7.1]),

$$\left(\sum_{N \leq x} r_{\mathcal{S}}(N)\right)^2 \leq \sum_{\substack{N \leq x \\ r_{\mathcal{S}}(N) \geq 1}} 1 \sum_{N \leq x} (r_{\mathcal{S}}(N))^2.$$

Of course $\sum_{\substack{N \leq x \\ r_{\mathcal{S}}(N) \geq 1}} 1 \leq \mathcal{A}(x)$. Therefore we can write,

$$\begin{aligned} \frac{\mathcal{A}(x)}{x} &\geq \frac{1}{x} \frac{\left(\sum_{N \leq x} r_{\mathcal{S}}(N)\right)^2}{\sum_{N \leq x} (r_{\mathcal{S}}(N))^2}, \text{ and so} \\ \frac{\mathcal{A}(x)}{x} &\geq \frac{1}{x} \frac{\left(c_1 \left(\frac{x}{\log \frac{x}{2}}\right)^2\right)^2}{c_2 \frac{x^3}{(\log x)^4}} = \frac{c_1^2 (\ln x)^4}{c_2 (\ln x - \ln 2)^4} \geq \frac{c_1^2 (\ln x)^4}{c_2 (\ln x)^4}. \end{aligned}$$

This means that $\mathcal{A}(x) \geq c_3 x$, for some positive constant c_3 and for all sufficiently large x . Since $1 \in \mathcal{A}$ it follows that \mathcal{A} has positive Shnirel'man density and so is a basis of finite order, say $h \in \mathbb{Z}^+$. Therefore every non-negative integer can be expressed as a sum of exactly h elements of \mathcal{A} . Whenever 0 occurs in such a sum we may write $0 + 0$ and whenever 1 occurs we may write $1 + 0$ and so any sum of exactly h elements of \mathcal{A} is a

sum of exactly $2h$ elements of $\mathcal{S} \cup \{0, 1\}$. Therefore, $\mathcal{S} \cup \{0, 1\}$ is a basis of order $2h$.

Theorem 4.9 *Let S be a subset of Π which contains a positive proportion of Π . If $2 \in S$ then, \mathbf{R} , the subring of \mathbb{Q} generated by $\{\frac{1}{p} \mid p \in S\}$ has finite unit sum number. \square*

Proof: By Lemma 4.8, the set $S \cup \{0, 1\}$ is a basis of finite order, say of order $h \in \mathbb{Z}^+$. For an arbitrary element r of \mathbb{Z}^+ we have:

$$r = s_1 + s_2 + \dots + s_h \quad (s_i \in S \cup \{0, 1\}, i = 1, \dots, h).$$

If $s_i \in S \cup \{1\}$ for all $i = 1, \dots, h$ then r is a sum of h units of R .

If $s_1, \dots, s_k \neq 0$ for some $1 \leq k < h$ and $s_{k+1}, \dots, s_h = 0$ then,

$$r = \sum_{i=1}^{k-1} s_i + s_k \left(\frac{1}{2^{h-k}} + \sum_{j=1}^{h-k} \frac{1}{2^j} \right)$$

is a sum of h units of \mathbf{R} . By Lemma 2.3, \mathbf{R} has the h -sum property. So, certainly $\text{usn}(\mathbf{R}) \leq h$. \square

This is a significant result. For example, letting $\Pi = \{p_i\}_{i=1,2,\dots}$ under the natural ordering, the ring generated by $\{\frac{1}{p_1}, \frac{1}{p_n}, \frac{1}{p_{2n}}, \dots, \frac{1}{p_{in}}, \dots\}$ has finite unit sum number whatever $n \in \mathbb{Z}^+$. (Note, $\mathbf{R} = \mathbb{Q}$ for $n = 1$.)

From the Prime Number Theorem (see Prachar [13, **III**, Theorem 2.4]) and the Prime Number Theorem for Arithmetic Progressions (see Prachar [13, **IV**, Theorem 7.5]) it is seen that;

$$\lim_{x \rightarrow \infty} \frac{\pi(x, k, l)}{\pi(x)} = \frac{1}{\varphi(k)},$$

where $\pi(x; k, l)$ denotes the number of rational primes congruent to $l \pmod k$ and not exceeding x ($k, l \in \mathbb{N}$, $(k, l) = 1$) and where φ is the Euler function.

So, for any $\varepsilon > 0$, we can find $x_0 \in \mathbb{R}$ such that

$$\varepsilon < \frac{\pi(x, k, l)}{\pi(x)} - \frac{1}{\varphi(k)} < \varepsilon \quad \text{for all } x > x_0,$$

so that $\pi(x, k, l) > \pi(x) \left(\frac{1}{\varphi(k)} - \varepsilon \right)$ for all $x > x_0$.

Now set $k = 24$, $l = 1$ and choose $\varepsilon = \frac{1}{16}$. Then $\pi(x, 24, 1) > \frac{1}{16}\pi(x)$ for all $x > x_0$ and for some $x_0 \in \mathbb{R}$.

Therefore the set of primes congruent to 1 mod 24 is a positive proportion of Π , and by Theorem 4.9 and Proposition 3.7 we have proved ,

Corollary 4.10 *Let $P = \{2\} \cup \{p \in \Pi \mid p \equiv 1 \pmod{24}\}$. Let G be a rational group such that $\mathbf{E}_{\mathbb{Z}}(G)$ is the subring of \mathbb{Q} generated by $\{\frac{1}{p} \mid p \in P\}$. Then $\text{usn}(G)$ is finite but greater than 2.*

It is possible to extend this approach to obtain an upper bound for the unit sum number of the above group G . Inevitably the bound so obtained is extravagantly large: it is shown in Meehan [10, **III** Proposition 3.15] that 1208000 is an upper bound.
