Perceived barriers of optometrists to glaucoma case findings in Ireland

Background: This research was designed to provide an in-depth exploration of the perceptions of optometrists relating to the challenges of glaucoma case finding in the Irish health-care system.

Methods: A survey was developed, piloted and distributed for anonymous completion by optometrists registered to practise in Ireland. The survey included 10 five-level Likert items exploring potential barriers to glaucoma detection and a free-text box for participants to comment more broadly.

Results: One hundred and ninety-nine optometrists (27 per cent of registrants) responded to the survey. Among the barriers identified, there was notable agreement (71 per cent) with the need for extra training on glaucoma detection. Logistic regression showed that optometrists without postgraduate qualifications were more likely to agree with the need for extra training (OR 3.2, 95% CI 1.3–8.1). Respondents largely agreed (61 per cent) that patient unwillingness to pay additional fees for supplementary glaucoma-specific tests was also a barrier. Appointment times of less than 30 minutes were significantly associated with six of the 10 proposed barriers to glaucoma detection. A logistic regression analysis (n = 179) confirmed that the time allotted per appointment was a significant predictor of the agreement time of optometrists as a barrier (χ² [1] = 13.92, p < 0.001). Multiple linear regression showed that optometrists with less experience, charging lower fees, and working in large multiples or franchised practices have the shortest appointment times.

Conclusion: The strong link found between postgraduate education and the confidence of optometrists in detecting glaucoma indicates that optometrists wishing to increase their scope of practice in the new legislative environment in Ireland may more actively seek training in areas of interest.

Optometrists play a vital role in the detection of glaucoma, the leading cause of irreversible blindness in the world. The most common glaucoma subtype, primary open angle glaucoma (POAG), is insidious, progressive and irreversible, presenting a significant public health challenge. In Ireland, approximately eight per cent of blind and partially sighted registrations are attributed to glaucoma. A study conducted in the west of Ireland showed an overall POAG prevalence of 1.88%, with prevalence rising to 3.2% in those older than 70 years. As our population grows and ages, and as life expectancy continues to rise, the burden of glaucoma will increase. Between 2006 and 2014, the Irish population grew by eight per cent and the number of people older than 65 years increased by 14 per cent, a trend which is predicted to continue and which will lead to an inevitable increase in the demand for glaucoma-related care.

As population screening for POAG detection is neither cost-effective nor feasible, detection is typically opportunistic. In countries where the optometry profession is well established, the responsibility for glaucoma detection largely falls to optometrists based in community practice. There are no available data for optometric glaucoma referrals in Ireland, but figures from the United Kingdom, where undergraduate training and practice patterns are relatively similar, show that between 90 per cent and 96 per cent of referrals to ophthalmology for suspect glaucoma originate from optometrists.

The difficulty of the role of the optometrist in the ophthalmic care pathway often goes unrecognised. It has been documented that optometrists are seen differently from other health-care professionals, as patients perceive the profession as having a commercial rather than a health-care role. The responsibilities of an optometric eye examination are broad, as optometrists are tasked with investigating and managing refractive and binocular vision anomalies, while also evaluating ocular health to detect ocular pathology including glaucoma.

Public perception of optometry practices as retail businesses with little to no health-care role affects credibility, which has an impact on patient education in relation to perceived utility of optometrist-recommended supplementary tests and recall visits, potentially affecting health-care outcomes. Additionally, optometric glaucoma referrals have been scrutinised over the past 25 years with a strong, arguably disproportionate, focus placed on false positive referrals.
Optometrists’ responsibilities to detect disease inherently lead to false positive referrals in a population where the relative prevalence of glaucoma is low,19,20 and this effect is likely to be compounded by a tendency for optometrists to preference sensitivity over specificity in their diagnostic testing.20 This practice pattern could be considered pragmatic, given that optometrists are required to detect pathology and are at risk of litigation21,22 if they fail in this duty of care.

It is understood that no medical test has perfect sensitivity and perfect specificity, and glaucoma detection is a particularly ambiguous area given the significant overlap in the clinical features of suspicious but normal individuals and those with early glaucoma.19,23 While decreasing false positive referrals for glaucoma would improve efficiency in a hospital eye-care service that is struggling to cope with demand,24 a myopic focus on false positive referrals could be detrimental. Repeated reports of false positive referrals could create a culture of diminishing sensitivity, where referrals are very specific but glaucoma diagnoses are missed because of reticence to refer or inability to carry out follow-up investigations.

This research aims to provide an in-depth exploration of the perceptions of optometrists of the challenges for glaucoma detection within the Irish health-care system. In case finding for glaucoma, optometrists face the challenge of detecting an insidious disease of relatively low prevalence,19 using tests with limited diagnostic accuracy.19,23 Identifying additional barriers to glaucoma detection in optometric practice can help inform and underpin the future service reform required to cater to the increasing demand for ophthalmic care. Consultation with the profession and investigation of any barriers to clinical practice for glaucoma, represent important precursors to the development of any new glaucoma care schemes.25,26

Once developed, the survey was validated. An external reviewer, with expertise in questionnaire design, first evaluated question construction to ensure that it did not contain leading, confusing or double-barrelled questions. A pilot survey was then sent to 20 community optometrists. The pilot group was selected at random from a group of 59 optometrists who had taken part in a Dublin-based glaucoma referral refinement scheme. Feedback from the pilot was incorporated into the final survey design.

The survey comprised three sections. The first section was designed to establish demographic information about the optometrists, such as mode of practice and academic qualifications, and to explore appointment times available for routine eye examination. The second section aimed to establish the range of equipment available within practices and to explore the level of confidence of optometrists in performing a range of pertinent examination techniques.

The final section addressed perceived barriers to glaucoma detection during routine eye examinations by optometrists. It contained 10 five-level Likert items that presented possible barriers that might be perceived by optometrists in relation to glaucoma detection. The Likert items were based on themes identified in a 2010 survey of UK-based community optometrists and which presented seven main barriers to optic detection of glaucoma.26 These barriers were expanded for our survey, to include 10 potential barriers (Table 2). Participants were asked to indicate their level of agreement or disagreement with each. A final free-text box was provided for participants to expand on the themes already suggested, or to express their own opinions on the barriers faced by optometrists.

A multi-mode method of distribution was used to maximise survey responses and minimise sampling bias.27 To capture responses from those who may be unlikely to volunteer to take part in an online or postal survey, the survey was launched in paper format at the Association of Optometrists Ireland (AOI) Annual General Meeting in November 2014. There was a nine-week running time for the survey, which ended in January 2015. All optometrists on the electronic data bases of the Federation of Ophthalmic and Dispensing Opticians (FOBO) and the AOI were sent a survey information leaflet, a link to the online survey in Google forms, and a printable version for those who preferred to return the survey by post.

The survey was anonymous. Practitioners were assured that all individual results would be kept strictly confidential. Participation in the survey was voluntary and completing the survey constituted informed consent. The study was approved by the Research Ethics Committee at Dublin Institute of Technology.

The data collected were analysed on the Statistical Package for Social Sciences (IBM SPSS Statistics for Windows, Version 22.0, Armonk, NY, USA) and RStudio (RStudio Team [2015]. RStudio: Integrated Development for R. RStudio Inc., Boston, MA, USA). The results were analysed using descriptive statistics and inferential statistics: Chi-square test of independence, multivariate ordinal regression, logistic regression and linear regression.

RESULTS

One hundred and ninety-nine optometrists responded to the survey, equating to 27 per cent of optometrists registered in Ireland (n = 754 at 25 July 2014). The study represents a large proportion of the optometrists registered to practise in Ireland, and has a margin of error of six per cent at the 95% confidence level. This falls within

Perceived barriers to glaucoma detection

Ninety-seven percent of participants responded to the Likert items proposing barriers to glaucoma detection in optometric practice and 94 per cent agreed with one or more of the suggested barriers. The most frequently cited barriers included the need for extra training (71 per cent agreement), patient unwillingness to pay for supplementary tests, defined as any diagnostic investigations that cannot feasibly be offered during a routine eye examination (examples might include repeat intraocular pressure measurements or full threshold automated perimetry) (61 per cent agreement), and poor continuity, caused by patients moving between practices (55 per cent agreement). The Likert items presented in the survey and the frequency of agreement with the proposed barriers are represented in Table 2.

Table 2 shows the frequency of agreement of optometrists with proposed barriers to glaucoma detection during routine eye examinations. The table displays the percentage of optometrists who agree, neutral, or disagree with each barrier. The most common barriers include training needs, financial constraints, and time limitations. The data are presented in a tabular format, with columns for Agree, Neutral, and Disagree frequencies.
To examine the relationship between the group demographics and agreement with the proposed barriers, a Chi-square test for association was conducted. Agreement with the need for extra training was significantly associated with postgraduate education. Optometrists without postgraduate qualifications were more likely to agree with the need for extra training in glaucoma detection (OR 4.3, 95% CI 1.7–11.6), $\chi^2 p = 0.003$.

Agreement with a lack of continuity of care as a barrier to glaucoma detection was associated with both employment status and time allowance per appointment. Employees were statistically significantly more likely to agree with a lack of continuity (OR 2.2, 95% CI 1.1–4.6, $\chi^2 p = 0.029$), than self-employed persons or those in managerial roles, as were optometrists with shorter appointment times (<30 minutes), who were more likely to agree with lack of continuity (OR 3.0, 95% CI 1.2–7.4, $\chi^2 p = 0.015$) than those with more time.

Time allowance per appointment emerged as the variable that was significantly associated with the most barriers (n = 6). Those optometrists with an appointment slot shorter than 30 minutes (26 per cent) were statistically significantly more likely to agree that time constraints, equipment levels, staffing and management issues, inadequate record keeping, financial constraints and lack of continuity of care all limit their ability to detect glaucoma in routine practice (OR 2.9 to 6.6, $\chi^2$, $p < 0.025$ for all).

The results of the full Chi-square analysis are shown in Table 3.

Regression analysis
Logistic and linear regression analyses were conducted to allow continuous variables to be incorporated into the analysis, to maintain the Likert scale ratings of the proposed barriers and to incorporate the effects of confounding factors.

Perceived need for extra training
To explore the impact of potential confounders on the perceived need for extra training, a cumulative odds ordinal logistic regression with proportional odds was run to establish the adjusted ORs for completed postgraduate education, subjective competence on binocular indirect ophthalmoscopy (BIO), tonometry equipment available, years since qualification, number of optometrists working within one practice, and access to financial support for continuing professional development (CPD) on the dependent variable, the perceived need for extra training.

The final model statistically significantly predicted the dependent variable over and above the intercept-only model ($\chi^2 (7) = 14.656$, $p = 0.041$). The adjusted odds of optometrists without postgraduate education agreeing with the statement that they needed extra training for glaucoma detection was 3.2 (95% CI 1.3–8.1) times that for optometrists with postgraduate education ($\chi^2 (1) 6.204$, $p = 0.013$). Therefore, postgraduate education remained as a significant predictor of agreement with the need for extra training, even when potential confounding factors were included in the analysis.

The remaining predictor variables used in the regression model were not significant. The model is shown in Table 4.

Short appointment times
A logistic regression was conducted, incorporating the full time range of appointment slots (removing outliers) to further analyse the effects of appointment duration as a barrier. The analysis was conducted for 179 optometrists, and found that the test of the full model against a constant only model was statistically significant. Time slot allotted, per appointment reliably distinguished between agree and disagree (or neutral) responses relating to whether optometrists have enough time to conduct a ‘full’ test ($\chi^2 (11) = 13.52$, $p < 0.001$). For estimate values, see Table 5. Figure 2 shows the probability of disagreeing with time constraints as a barrier (probability of no barrier) versus the appointment slot time, and shows that an appointment time of ~45 minutes would result in a 75 per cent probability of no barrier to diagnosis.

A multiple linear regression was conducted to identify those optometrists most likely to be affected by short appointment times. Fees charged per eye examination, years since qualification and mode of practice (independent private practice versus large multiples or franchises) all proved to be significant predictors of the amount of time available to optometrists per eye examination. R² for the overall model was 42.2 per cent with an adjusted R² of 41.1 per cent, a large size effect. The multiple regression model statistically significantly predicted the time per appointment slot (F [3, 158] = 38.412, $p < 0.0001$). All three variables added statistically significantly to the prediction, $p < 0.05$. Regression coefficients, standard errors and exact p-values are shown in Table 6.

The model shows that optometrists with less experience, charging lower fees, and working in large multiples or franchised practices have the shortest appointment times. Using the regression model to predict appointment times illustrates the effects of each independent variable, showing that years of experience had a small although statistically significant effect on the appointment time, while mode of practice had a large effect: optometrists working in independent practice, charging £30 for a sight test with 10, 20 and 30 years of experience are predicted to have an appointment slot of 30.80 (95% CI 29.30–32.30), 31.97 (95% CI 30.75–33.19) and 33.1 (95% CI 31.63–34.65) minutes, respectively. For optometrists working in a franchise or multiple, charging £30 for a sight test with 10, 20 and 30 years of experience, the predicted test time is substantially shorter, at 22.92 (95% CI 20.73–25.11), 24.09 (95% CI 21.84–26.33) and 25.26 (95% CI 22.64–27.87) minutes, respectively.

The final element in the survey was a free-text box, in which respondents could elaborate on their responses or suggest other barriers to glaucoma detection. Nine percent of respondents completed the free-text box. The most commonly cited barrier was a lack of finance or time for diagnostic tests (41 per cent). Specific mentions included shortfalls of state funding and unwillingness of patients to pay supplementary fees as a restriction to buying equipment and giving extra chair time for enhanced or repeated diagnostic tests. Thirty-one percent of respondents cited poor care pathways, including lack of structured referral pathways and absence of multidisciplinary cooperation as a barrier.

DISCUSSION
The key findings to emerge from our study include:
- the perceived need for extra training in glaucoma detection and the clear link between a perceived need for training and a lack of postgraduate education

**Perceived barriers to glaucoma detection**

**Training needs**

The high frequency of agreement (%), with the need for extra training in examination routines relating to glaucoma detection, suggests that training is perceived as available but is still a need. The use of Likert items in our survey may have influenced responses, where conscientious practitioners were inclined to agree that further training would improve their ability to detect glaucoma. It is possible that lack of training might be partly explained by the difference in questionnaires used in the two studies: Myint and colleagues assessed barriers to glaucoma detection through qualitative analysis of results of a free-text questionnaire, whereas we conducted a survey with Likert items. Both studies found that time and financial constraints were the most commonly stated barriers.

In the UK, only 15% of respondents agreed that training was a barrier. The results of a survey among optometrists working in the UK could have generated higher levels of agreement with the need for extra training, whereas uptake of postgraduate qualifications already obtained by optometrists working in the UK might be partly explained by the difference in questionnaires used in the two studies. Myint and colleagues assessed barriers to glaucoma detection through qualitative analysis of results of a free-text questionnaires, whereas we conducted a survey with Likert items. Both studies found that time and financial constraints were the most commonly stated barriers.

Fifteen per cent of the respondents found that training is perceived as available but is still a need. The use of Likert items in our survey may have influenced responses, where conscientious practitioners were inclined to agree that further training would improve their ability to detect glaucoma. It is possible that lack of training might be partly explained by the difference in questionnaires used in the two studies: Myint and colleagues assessed barriers to glaucoma detection through qualitative analysis of results of a free-text questionnaires, whereas we conducted a survey with Likert items. Both studies found that time and financial constraints were the most commonly stated barriers.
not being availed of, so the difference in 
uptake of postgraduate education is 
unlikely to be accounted for by lack of 
access alone.

In the UK, optometrists can participate 
in a variety of enhanced service schemes, and 
examples of which include glaucoma 
repeat measures, referral refinement and 
comanagement, many of which 
require postgraduate training. It is possible 
that the lack of extended scope roles in Ireland 
has resulted in a relatively lower level of 
uptake of postgraduate training. Within 
our free-text response spaces, two optometrists 
noted that they would consider structured postgraduate training only if shared care, or enhanced scope schemes became a reality in Ireland.

At the time of the survey, optometrists in Ireland were constrained in their scope of practice by a restrictive and arguably archaic legislation, which obliged optometrists to refer patients to a medical practitioner once the minimum index of suspicion for pathology was met and stated: ‘[A] registered optician who is not a registered medical practitioner shall 
not suggest by any written or oral statement or by any action that the registered optician has made or is capable of making a medical diagnosis of a disease of the eye or that, in relation to the treatment of the eyes, the registered optician has done or is capable of doing anything other than:
A. in the case of a registered optometrist, the prescribing or provision of spectacles, or
B. in the case of a registered dispensing optician, the provision of spectacles.’

Optometrists practising within this context may have felt discouraged from expanding their clinical skill and expertise, and may have considered themselves ‘over-trained’ for the role defined by the 1956 legislation.

This legislation was repealed on 31 October 2015, being replaced by the Health (Miscellaneous Provisions) Act 2015, and regulation of optometry was transferred to a new multi-profession health regulator called CORU. Under the new legislation, scope of practice has been defined loosely, stating that professionals must ‘act within the limits of (their) knowledge, skills, competence and experience’ and ‘practise only in areas in which (they) have relevant competence, education, training and experience’. Within this framework, there is clear scope for optometrists, with the appropriate skills, to become more involved in the diagnosis, monitoring and management of ocular pathology. In this new environment, Irish optometrists might feel more motivated to engage in further education and training, as any new skills can now be put to use in areas of personal interest. A UK survey found that 42.7 per cent of optometrists identified a special interest in a particular area of optometry, and 69 per cent of these respondents wished to undertake further training in the field of interest.29 The top area of special interest was glaucoma.

Even those optometrists who may not feel inclined to partake in structured postgraduate education will need to meet a new statutory requirement for CPD. The new optometric regulatory body, CORU, requires 30 hours of CPD in a 12-month period, with the first cycle beginning on 1 April 2017. Educators should consider this potential extra demand for postgraduate education in Ireland, and further analysis into the types of training that can develop real improvements in clinical competence should be prioritised. Any new educational opportunities should be developed in consultation with the profession, to ensure that the identified need for extra training is appropriately addressed. Consideration should also be given to the design and content of the undergraduate degree program, to ensure that newly qualified optometrists are appropriately trained in glaucoma detection and also equipped with the skills to engage in and take responsibility for their own continuing professional development.

Very few of the optometrists surveyed had glaucoma-specific qualifications; just six of the 30 respondents with completed postgraduate education had completed a glaucoma module or certificate, although only 14 of the 30 gave enough detail in their answer so that the exact type of postgraduate qualification could be discerned. Respondents were considered to have completed postgraduate education if they had completed a Level 9 or 10 postgraduate course in any area relating to optometric practice, including modules, certificates, diplomas, clinical masters or PhDs.

Interestingly, any form of postgraduate education (as defined above) appeared to increase optometrists’ confidence in their ability to detect glaucoma. They were less likely to agree with the Likert item ‘I need extra training’. Perhaps this indicates that those optometrists who have sought postgraduate education are more independent, life-long learners, and even if they have not

Financial constraints

Patient unwillingness to self-fund supplementary diagnostic tests within optometry practices was the second most frequently perceived limitation to case findings of optometrists for glaucoma. A similar theme emerged in free-text responses, where shortcuts of state funding as well as the unwillingness of patients to pay supplementary fees, were identified as barriers to buying equipment and giving extra ‘chair time’ for enhanced diagnostic tests. Optometrists could potentially improve patient uptake of supplementary testing by improving patient education, putting emphasis on the importance of detecting insidious disease and emphasising the clinical rather than the commercial aspects of their service.

Shah and colleagues found that only a minority of optometrists discussed glaucoma risk factors with a patient of African racial decent, even when the standardised patient asked the optometrist if she was at greater risk of any eye conditions. They showed that patient education by optometrists is likely to be underutilised and inconsistent. However, even if patient education was significantly improved, the funding structures within the health-care system may incentivise patients to seek referral to secondary care, where appointments are free, rather than self-fund diagnostic testing within an optometry practice.

In Ireland, the state is the largest single purchaser of optometry services, subsidising eye examinations and optical appliances through a variety of schemes. When the survey was conducted, the contracts did not allow or pay for repeat appointments to refine clinical decision-making, so patients found suspect for glaucoma had to pay for follow-up appointments—for example, repeated visual fields or tonometry measurements—or the practice provided these services with no additional remuneration. Public hospital services including ophthalmology outpatient departments are free to all, subject to small co-payments. This financial incentive, coupled with the considerable pressure optometrists are under to detect every case of sight-threatening disease, naturally leads to false positive referrals to secondary care.

Low-risk patients, who might suitably undergo further investigations and monitoring within community optometry, may be added to the long waiting list for public ophthalmology outpatient appointments. This circumstance has been studied by Tuck, who found that 74 per cent of the patients referred by an optometrist with ‘almost definite’ glaucoma were confirmed as having the condition, compared with only 21 per cent of those with ‘possible’ glaucoma.

Recent contract negotiations have led to significant modernisation of the contractual agreements between the Department of Social Protection and those optometrists agreeing to provide state-funded eye examinations. On 4 April 2017, a notification was issued declaring that the primary eye examination fee was to be increased from €22.42 to €30.00, and a further €20 (€30 if dilation is required) would be paid for a follow-up or repeat appointment. This represents an important change in the current funding of optometry practices, which could have a significant impact on optometric glaucoma case findings procedures, potentially facilitating more accurate diagnostic testing within community-based optometry practices. The significant increases in funding may affect both the time and equipment available to optometrists in community practice. Our Chi-square analysis (Table 3) shows that optometrists charging less than €30 for a private eye examination were significantly more likely to agree with the Likert item ‘the equipment available where I work is inadequate; this limits the accuracy of my glaucoma exam.’ The new fee structures demonstrate recognition of the primary eye-care services provided by optometrists, and they may represent a watershed moment in clinical practice patterns. Future work should look to map the changes in practice norms that emerge from the increased funding of optometry services in Ireland.

It stands to reason that optometrists with shorter appointment times would feel that time constraints limit their abilities to detect glaucoma and the logistic regression (Table 5, Figure 2) confirmed that time per appointment was a significant predictor of agreement with this barrier. It is also important to note that this same group identified many more barriers, which highlights the importance of time as a facilitator of comprehensive and effective clinical practice.

Time since registration was found to be a significant predictor of sight test time, where optometrists with less experience are more likely to have shorter appointment times. It is possible that younger or more junior optometrists are more susceptible to pressure from management to deliver faster eye examinations. Senior or more experienced clinicians may have more confidence in dictating
suitable appointment times, or may be in the
disposition of setting their own appointment
diaries. Although there was a much higher
proportion of less experienced optometrists
working in large retail groups or franchises,
which tended to have shorter appointment
times compared to independent private
practices, the regression shows that time
since registration is a significant predictor of
time test even when this confounding factor
is adjusted for (Table 6).

Davey and colleagues\(^{15}\) examined the
factors influencing false positive referrals
from optometrists and found that clinician
experience had the greatest effect on refer-
ral accuracy, where inexperienced optome-
trists were more likely to generate false
positive referrals to ophthalmology. Shorter
appointment times for inexperienced opto-
metrists might contribute to this effect,
where less experienced optometrists, who
might be more uncertain of a diagnosis,
also have less time to refine their clinical
decision-making, making them more likely
to make unnecessary referrals.

The factor which had most effect on the
time per appointment was mode of prac-
tice, where optometrists working in large
multiples or franchises were predicted to
have significantly shorter test times than
those in independent private practice. The
assumption one could draw from this is
that franchised practices and large retail
groups have a higher volume of patients,
and optometrists are under pressure to
produce faster eye examinations, but other
factors might also be at play. Multiples
often have more ancillary staff members
who can carry out preliminary testing prior
to the eye examination. This can shorten
examination times significantly and is argu-
ably a better use of time spent by the
optometrists.

There may also be a significant differ-
ence in the patient populations of the dif-
ferent types of practices, representing a
type of causality dilemma. It is possible that
more ‘straightforward’ patients tend to
present to multiples or franchises, whereas
patients who perceive their issues as more
complex, tend to present to independent
optometry practices that may be perceived
as more competent or clinically experi-
enced, given that there is a much higher
proportion of more experienced optome-
trists working in independently owned busi-
nesses. Therefore, the shorter appointment
times reported by those in multiples or
franchised practices may result from their
less complex patient base, or vice versa.
However, the fact remains that shorter
appointment slots appear to influence the
perceptions of optometrists of the barriers
that exist to glaucoma detection. Although
the Association of Optometrists Ireland
advises that eye examinations should not
take less than 20 minutes,\(^{40}\) our findings
suggest that a sight test time of 30 minutes
or longer is more appropriate, which falls
in line with recommendations from the
Scottish General Ophthalmic Services.\(^{41}\)

State financing of extra time for diagnos-
tic testing within community optometry
could facilitate more accuracy in referrals
to secondary care, which would be likely to
result in a net saving for the state\(^{32}\) while
also relieving the significant psychological
burden\(^{42}\) created by unnecessary referrals.
The recent renegotiation of eye examina-
tion fees may serve to address the time and
finance issues identified; similar repeat
measures schemes have proved to be a
cost-effective\(^{43}\) intervention in the glau-
coma care pathway. It will be interesting to
observe how the increased funds are imple-
mented across various practice settings,
and whether increased fees will result in
improved equipment levels and increased
appointment times, or perhaps just become
assimilated into the business without any
discernible change to service provision.

Limitations
Surveys are vulnerable to both sampling
and response bias, and a healthy degree of
scepticism toward survey data is often
appropriate. The methodology used within
our survey aimed to minimise bias, and the
demographics of the respondents do
appear representative in terms of geo-
graphic location and time since qualifica-
ation. Being aware of the potential for bias,
particularly voluntary response bias where
the survey can over-represent individuals
with strong opinions, we have conducted a
conscientious and judicious analysis of the
survey responses.

CONCLUSIONS
This paper is the first in-depth exploration
of perceptions of optometrists of the bar-
riers to glaucoma detection in community
practice in Ireland. The research took place
at a critical time for Irish optometry, taking
stock of practice norms prior to the enact-
ment of landmark legislation, which may
usher in significant developments in the
scope of practice over the coming years.

Any change in scope of practice will need to be underpinned by appropriate
training, education and experience, and
responses of optometrists to the survey
show a clear acknowledgement of the link
between further education and improving
clinical practice. To deliver real improve-
ments in clinical competence, the type of
training made available should be carefully
considered by educators and legislators in
Ireland.

The responses also identified financial
constraints on clinical practice that may be
addressed by the recent renegotiation of
eye examination fees in Ireland. Increased
fees and repeat measures allowances may
serve to provide more equitable access to
refined clinical decision-making. Increases
in the standard eye examination fee might
be best used to facilitate longer appoint-
ment times, so that optometrists, including
younger graduates and those working in
multiples, are not burdened with examina-
tion times that limit their perceived ability
to detect glaucoma. Future research should
build on the findings presented in this
