Abstract

New ferrocene derivatives, (6-(4-(1H-pyrrol-1-yl)phenoxy)hexyl) ferrocene (**1**) and ((4-(1H-pyrrol-1-yl)phenoxy)carbonyl) ferrocene (**2**) were synthesised, characterised and electrochemically evaluated as redox active films formed via anodic oxidation with pyrrole. Thin film studies were conducted and films formed from both compounds resulted in a stable Fe^{III/II} redox couple with $E^{\circ} = 0.035\text{V}$ and 0.365V vs. Ag/Ag^+ for (**1**) and (**2**) respectively. Both potential sweeping and chronocoulometry were employed for film formation with the former resulting in controllable, reproducible film deposition. Growth conditions and solution concentrations were varied in order to assess influence on electrochemical behavior. Surface coverage's were of the order 10^{-8} - 10^{-9} mol cm^{-2} , surface confined behavior (i_p vs. v) was evident up to 0.2 V s^{-1} with semi-infinite diffusion (i_p vs. $v^{1/2}$) dominating at higher scan rates. Laviron theory was employed where possible for the determination of electron transfer co-efficient and rate constants.

For Peer Review Only

Introduction

Organometallic compounds, particularly metallocenes, have established a significant role in a range of sensor applications over recent decades (Forrow 2005). Unlike other organometallic compounds, the properties of metallocenes, in terms of electrochemistry in particular, can readily be modified by substitution on one or both cyclopentadienyl rings. A recent review describes polymers with conjugated matrices which incorporate metallocene complexes with two cyclopentadienyl ligands and their derivatives (Vorotynstev 2008).

A wide variety of heterocycles bearing tethered ferrocene groups have been prepared and electropolymerised to form conducting electroactive polymers, with a range of applications (Chen 2002). Pyrroles are excellent monomers for the electropolymerisation of polymer films containing redox active centers, and the synthesis and applications of polypyrrole films containing metal complexes have been reviewed (Deronzier 1996). The binding of electrocatalytically active redox species within conducting polymer films opens up possibilities for the design of electron transfer pathways between immobilised enzymes and electrode surfaces (Schuhmann 1997). Other reports of redox active copolymer films include long and short chain osmium and ruthenium bipyridine modified pyrrole derivatives (Warren 2008, Habermuller 2000, Reiter 2001, Schuhmann 1993, Ochmanska 1989).

Ferrocene and their derivatives have made frequent appearances in reviews and reports on biosensors as redox mediators (electron shuttles) for rapid electron transfer between

1
2
3 active sites of enzymes and electrodes (Vorotyntsev 2008, Hudson 2001, Rahman 2008).
4
5 Due to a combination of catalytic efficiency, stability in the reduced form, pH
6
7 independent redox potentials, ease of synthesis and versatility of substitution, ferrocene
8
9 exceeds other organometallic compounds with respect to biosensor applications.
10
11 Moreover, ferrocenes are small in size and sufficiently mobile to penetrate the enzyme
12
13 active site (Forrow 2002). However, with its chemical structure of two π -bonding
14
15 cyclopentadienyl rings, ferrocene itself is naturally hydrophobic, limiting its use in
16
17 aqueous media. Intensive efforts have been made to modify one or both of the π -bonding
18
19 cyclopentadienyl rings in order to render ferrocene more hydrophilic or otherwise more
20
21 suitable as a redox mediator (Laselle 1994 and Cass 1984).
22
23
24
25
26
27
28

29 It is well known that the nature of substituents affects the redox potentials of ferrocenes,
30
31 i.e. electron withdrawing groups, such as carboxylic acids or carbonyl groups, shift $E_{1/2}$ in
32
33 the anodic direction, while electron donating substituents, such as methyl- or amino, shift
34
35 $E_{1/2}$ in the cathodic direction (Tustin 2007 and Forrow 2002). The charge on ferrocene
36
37 also plays an important role in its ability to act as a mediator. No direct correlation
38
39 between the mediation rate constant (k_{med}) and the redox potential of the ferrocene
40
41 derivatives has been observed (Bartlett 1991 and Ryabov 2001). Hence, ferrocene
42
43 derivatives of low redox potentials do not necessarily possess high k_{med} values.
44
45 Conversely, biosensor systems of high redox potential are susceptible to interference in
46
47 real samples and, more importantly, can be fouled at a high substrate concentration (Ruan
48
49
50
51
52
53
54
55

60
2001).

1
2
3 Forrow et al 2002, reported synthesis and characterisation of a series of
4 ferrocenylaminoalcohols in a search for suitable redox mediators for glucose biosensors.
5
6 In their report, the electrochemical and kinetic data of the ferrocene derivatives were
7
8 tabulated to study the influence of the substituents in ferrocene on redox potentials and
9
10 mediation rate constant. It was agreed that the electronic effects of the substituents
11
12 influence the redox potentials of the ferrocene derivatives but the effects diminish if the
13
14 substituents were too far ($n > 3$ or 4) from the ferrocene molecule. The degree of
15
16 solubility in aqueous medium is dependent on the nature of substituents, e.g. $\text{NH}_2 > \text{OH} >$
17
18 CONH_2 .
19
20
21
22
23

24
25
26
27 An electrochemical enzyme (glucose oxidase) electrode based on a ferrocene-containing
28
29 redox polymer (ferrocene-containing cross-linked polyallylamine) was cross-linked using
30
31 glutaraldehyde and bovine serum albumin (BSA) on a glassy carbon electrode surface.
32
33 The electrochemical behavior of the redox polymer was found to be almost completely
34
35 based on a semi-infinite diffusion process (Koide 1991). Brown et al developed
36
37 electropolymerised films of tetraaminophthalocyanine (TAPc) with ferrocene (Fc), which
38
39 produced a three-dimensional network of Fc active sites used for the detection of glucose.
40
41 Following polymerisation, glucose oxidase was immobilised onto the TAPc/Fc films and
42
43 the biosensor was then employed in the detection of glucose (detection limit 5 μM).
44
45 Under stirred conditions, the biosensor reached a limiting current in approximately 10–15
46
47 s (Brown 2005). Naruhide et al 2008 reported the application of electrodeposited single-
48
49 wall carbon nanotubes (SWCNT) as an immobilisation matrix for the construction of an
50
51 amperometric glucose biosensor. The SWCNT attached electrode surface was
52
53
54
55
56
57
58
59
60

1
2
3 subsequently modified with glucose oxidase (GOD) and 11-(ferrocenyl)-
4 undecyltrimethylammonium bromide (FTMA). The formation of the biosensor was
5 controlled by constant potential electrolysis. The cyclic voltammetric results implied that
6 direct electron transfer occurred between the active centre of immobilised GOD and the
7 modified surface of the electrode. The electron-transfer coefficient was 0.70 ± 0.3 and
8 electron-transfer rate constant was evaluated to be $2.69 \pm 0.03 \text{ s}^{-1}$. The electrode retained
9 78.62% of its initial response after 50 cycles.

20
21
22 Having taking into account recent literature and the trends observed with various electron
23 donating/withdrawing substituents (Forrow 2002) incorporated into ferrocene, several
24 candidate structures were selected for synthesis and characterisation. These include (6-(4-
25 (1H-pyrrol-1-yl) phenoxy) hexyl) ferrocene (**1**) and ((4-(1H-pyrrol-1-yl) phenoxy)
26 carbonyl) ferrocene (**2**) which will be the subject of this study. The attached pyrrole
27 monomer unit facilitated polymer growth via co-polymerisation with pyrrole to form
28 redox active polymer films. This investigation forms the first step in the evaluation of
29 these immobilised redox species as potential candidates for effective oxidase enzyme
30 (glucose/glutamate) mediation.

13
14 Melting point analyses were carried out using a Stewart Scientific SMP1 melting point
15 apparatus and were uncorrected. Elemental analyses were carried out at University
16 College Dublin, Dublin, Ireland. Infrared spectra were obtained from a Nicolet *Impact*
17 410 FT-IR spectrometer using the Omnic software. Solid samples were prepared as
18 dispersion in KBr disks. ^1H and ^{13}C NMR spectroscopy were carried out on a Joel JNM-
19 LA 300 FT-NMR 300 MHz spectrometer using CDCl_3 as the solvent unless stated, and
20 tetramethylsilane (TMS) as the internal standard. Chemical shifts were expressed in parts
21 per million (δ) downfield from the internal standard. Cyclic voltammetry and
22 amperometry experiments were carried out using CH instruments CHI 660, CHI 750,
23 CHI 420 and CHI 900 potentiostats. A single-compartment electrochemical cell was used
24 with a glassy carbon working electrode, a platinum counter electrode and $\text{Ag} / \text{AgCl} | \text{KCl}$
25 (3 M) reference for aqueous solutions. For the non-aqueous solutions, the reference
26 electrode used was a silver wire in contact with a solution of acetonitrile and AgNO_3 (10
27 mM) and 0.1 M of the same supporting electrolyte as employed in the cell and was
28 referred as $\text{Ag} | \text{Ag}^+$.

Synthesis of (6-(4-(1H-pyrrol-1-yl) phenoxy) hexyl) ferrocene (1)

Anhydrous potassium carbonate (1.38 g, 10 mmol) and 4-(1H-pyrrol-1-yl) phenol (0.64 g, 4 mmol) were added to a stirred solution of acetonitrile containing bromohexylferrocene (1 g, 3 mmol). The reaction mixture was then refluxed under nitrogen for 36 h. The reaction mixture was cooled to room temperature and filtered under reduced pressure. The filtrate was dissolved in 6 mL dichloromethane and finally triturated in 10 mL methanol to produce a bright yellow solid. The product mixture was filtered and the yield was 1.13 g (92%).

TLC (eluent: hexane: ethyl acetate, 90 : 10) revealed a spot with R_f of 0.51. m. p. 148 - 151 °C. Found C, 72.93; H, 6.78; N, 3.27; Fe, 13.95, requires C, 73.07; H, 6.84; N, 3.28; Fe, 13.07. $\nu_{\max}/\text{cm}^{-1}$ 2937 (N-H) 2454 (C-H) 1525 (C-O). δ_H (300 MHz, CDCl_3) 4.26 (5H, m, $H_c \times 5$), 4.52 (2H, d, $H_b \times 2$), 4.98 (2H, d, $H_a \times 2$), 6.35 (2H, d, $H_k \times 2$), 7.07 (2H, d, $H_j \times 2$), 7.04 (2H, d, $H_g \times 2$) and 7.33 (2H, d, $H_h \times 2$). δ_c 111.1 ($C_k \times 2$), 121.9 ($C_g \times 2$), 122.3 ($C_h \times 2$), 123.9 ($C_j \times 2$), 137.1 ($C_c \times 5$), 137.4 ($C_b \times 2$), 137.8 (C_i), 141.2 ($C_a \times 2$), 148.3 (C_f), 150.4 (C_d), 168.1 (C_e).

Synthesis of ([4-(1H-pyrrol-1-yl) phenoxy] carbonyl) ferrocene (2)

A mixture of ferrocenecarboxylic acid (0.46 g, 2.02 mmol), *N,N'*-dicyclohexylcarbodiimide (DCC) (0.60 g, 2.91 mmol), 4-(dimethylamino) pyridine (0.24 g, 1.97 mmol) and 4-(1H-pyrrol-1-yl) phenol (0.32 g, 1.98 mmol) were refluxed in 40 mL anhydrous dichloromethane. The reaction was carried out under nitrogen for 48 h. Subsequent to cooling the reaction mixture, 50 mL dichloromethane was added. The

1
2
3 mixture was filtered through a bed of silica. An additional 50 mL dichloromethane was
4
5 used to recover any desired product left in the silica bed. The solvent was then removed
6
7 under vacuum. To prompt recrystallisation, the residue was dissolved in a minimum
8
9 amount (~ 2 mL) of dichloromethane was added into methanol (~ 10 mL). The resulting
10
11 yellow powder was washed with hot hexane to get rid of traces of DCC. Following
12
13 filtration, the residue was recrystallised twice in a mixture of dichloromethane: methanol
14
15 (2 mL : 18 mL). The product was filtered and dried. The yield was 0.36 g (49%).

1
2
3 temperature. 3 mL of ferrocene derivative, ((4-(1H-pyrrol-1-yl)phenoxy)carbonyl)
4 ferrocene (**2**) or (6-(4-(1H-pyrrol-1-yl)phenoxy)hexyl) ferrocene (**1**) (1 – 5 mM) and
5 pyrrole (0.1 to 5 mM) in acetonitrile/0.1 M TBAPF₆ was cycled at 100 mV s⁻¹ for (1-5
6 cycles) on the surface of glassy carbon working electrode from -0.4 V to 1 V vs. Ag |
7 Ag⁺. Following polymer growth, the electrode was rinsed with acetonitrile to remove
8 unpolymerised material. The polymer films was then stabilised in a fresh solution of
9 acetonitrile/0.1 M TBAPF₆ over the range 0.2V to 0.7V for ferrocene derivative (**1**), -
10 0.2V to 0.4V for ferrocene derivative (**2**) for 25 cycles at 25 mV s⁻¹. A scan rate study (1
11 – 1000 mV s⁻¹) was performed for each film over the range 0.2V to 0.7V for ferrocene
12 derivative (**2**), -0.2V to 0.4V for ferrocene derivative (**1**). The films were also examined
13 in a number of aqueous buffers 0.1 M PBS pH 7.4, 0.1 M KCl in PBS pH 7.4 (0.1 M), 0.1
14 M Tris buffer pH 7.4, 0.1 M NH₄PF₆ and 0.1 M LiClO₄.

34 *Co-polymerisation of ferrocene derivatives and pyrrole using chronocoulometry*

35
36 A solution of 3 mL of ferrocene derivative, ((4-(1H-pyrrol-1-yl)phenoxy)carbonyl)
37 ferrocene (**2**) and (6-(4-(1H-pyrrol-1-yl)phenoxy)hexyl) ferrocene (**1**) (1 mM) and
38 pyrrole (0.5 mM) in acetonitrile/0.1 M TBAPF₆ was employed with the following
39 parameters: Potential: 0 (initial) and 0.65 V (final) with 1 step and pulse width of 1000
40 sec, sample interval of 0.063 sec. Following polymer growth, the co-polymer films were
41 stabilised using the same conditions as before.

Research and Discussion

Two new pyrrole-ferrocene derivatives with differing spacer linkages were prepared according to the synthetic routes described in Schemes 1 and 2. The ferrocene compounds used as starting materials were known compounds and commercially available. The originality of the synthetic routes reported here lies in the respective coupling reactions with 4-(1H-pyrrol-1-yl) phenol and their respective reaction conditions.

The shorter chain ([4-(1H-pyrrol-1-yl) phenoxy] carbonyl) ferrocene (**2**) was prepared using a modified Steglich esterification procedure using DCC and DMAP as condensing agent and catalyst respectively. The yellow solid product was isolated in moderate yield (49%), following recrystallisation and exhaustive washing with hexane to remove traces of un-reacted coupling reagent. Synthesis of the longer chain (6-[4-(1H-pyrrol-1-yl) phenoxy] hexyl) ferrocene (**1**) was effected by O-alkylation of the aforementioned pyrrolyl phenol using mild reaction conditions, namely K_2CO_3 in acetonitrile. The reaction was complete in 36 hours, and the product was isolated as a bright yellow solid in 92% yield. The compounds were not water soluble but showed excellent solubility in polar solvents, in particular acetonitrile, and trace levels were soluble in buffer solutions such as $LiClO_4$, phosphate buffer, KCl, Tris and NH_4PF_6 .

Electrochemical characterisation of co-polymer films formed from 6-[4-(1H-pyrrol-1-yl) phenoxy) hexyl) ferrocene (2)

Compound (1) and (2) underwent one reversible redox process at $E^0 = 0.035$ V and 0.365 V with ΔE of 101 and 92mV respectively vs. Ag/Ag⁺ (in acetonitrile containing 0.1M TBAPF₆) (Figure 1(a) and (b)). The anodic limit was varied but it was not possible to grow a conductive electroactive film, nor could a clear current signal be obtained for the pyrrole group in the case of (2). Homopolymerisation of monomers bearing bulky groups close to the heteroaromatic ring fails in general (Schuhmann 1997) as was found in the case of both compounds (1) and (2), therefore co-polymerisation using pyrrole was carried out. The co-polymerisation approach enables species with just one pyrrole group to be used, uses lower polymerisation potentials and it is also possible to vary the metal complex content of the resulting co-polymer film (Ochmanska 1989).

Electropolymerisation of pyrrole can be achieved using potential sweeping leading to electrodeposition of a stable adherent polymer film, obtained in an oxidised state which is electrically conducting. The oxidised state contains approximately one positive charge for every 3-4 pyrrole rings (Deronzier 1996). Novel ferrocene derivatives, ((4-(1H-pyrrol-1-yl)phenoxy)carbonyl) ferrocene (2) and (6-(4-(1H-pyrrol-1-yl)phenoxy)hexyl) ferrocene (1) were co-polymerised with pyrrole in acetonitrile containing 0.1 M tetrabutylammonium hexafluorophosphate (TBAPF₆) by anodic oxidation, to produce electroactive conducting polymer films on glassy carbon electrodes. Following electropolymerisation, the films were washed to remove any unbound monomer and characterised using cyclic voltammetry.

1
2
3
4 In order to optimise the ratio of the ferrocene derivative:pyrrole in the growth solution,
5
6 experiments were conducted over a range of concentration of ferrocene derivative (1-5
7
8 mM), while the concentration of pyrrole varied from 0.1-5 mM. The effect of the number
9
10 of cycles (1 to 5 cycles) during co-polymerisation was also examined, in order to
11
12 determine the effect of thickness on electrochemical behavior of the films. Following
13
14 polymer growth, the polymers were stabilised in fresh electrolyte (0.1 M TBAPF₆/ACN)
15
16 by repeated cycles at a scan rate of 25 mV s⁻¹ for 25 cycles. A subsequent scan rate study
17
18 was performed on each film over the range 1 to 1000 mV s⁻¹. The resulting polymers
19
20 showed excellent stability in 0.1 M TBAPF₆/ACN and *i*_p vs. scan rate, *v*, was linear up to
21
22 200 mV s⁻¹ with semi-infinite diffusion limiting the current at higher scan rates (*i*_p linear
23
24 with respect to *v*^{1/2}).
25
26
27
28
29
30
31

32 **Figure 2(a)** displays the cyclic voltammogram for polymer growth of (6-(4-(1H-pyrrol-1-
33
34 yl)phenoxy)hexyl) ferrocene (**1**) (5 mM) and pyrrole (5 mM) in 0.1 M TBAPF₆-ACN
35
36 over 5 cycles with the Fe^{2+/3+} redox process evident at E_{1/2} = 0.05V vs. Ag/Ag⁺,
37
38 followed by a rise in current over the range 0.6-1V vs. Ag/Ag⁺ indicating the oxidation of
39
40 (**1**) prior to the pyrrole monomer. The cyclic voltammograms obtained showed the
41
42 expected increase in current with increasing number of cycles consistent with the growth
43
44 of an electroactive polymer. The electrochemically induced formation of conducting
45
46 polymer films on an electrode surface involves diffusional transport of the monomer to
47
48 the surface, its oxidation at an appropriate electrode potential to a radical cation, radical-
49
50 radical coupling, electrochemical oxidation of the oligomers formed, chain propagation
51
52 and finally precipitation of the polycationic polymer (Schuhmann 1997). When the
53
54
55
56
57
58
59
60

1
2
3 cathodic potential sweep reached +0.8V, the cathodic current was greater than the anodic
4
5 indicating that a chemical reaction had occurred i.e. nucleation of polymeric structures
6
7
8 onto the surface of the electrode.
9

10
11
12 Films were also formed at 1 and 2 cycles and **Figure 2(b)** shows the cyclic
13
14 voltammogram of a 1 cycle polymer film, following growth, cycled in a fresh solution of
15
16 0.1 M TBAPF₆/ACN over the range -0.2 V to 0.4 V at a 25 mV s⁻¹ (25 cycles). Overlaid
17
18 on the same figure is a polypyrrole film formed (in the absence of **(1)**) under identical
19
20 conditions with evidence of the conducting polymer background signal. E⁰ for the
21
22 immobilised species Fe^{II/III} was 87mV vs. Ag/Ag⁺ resulting in a 122 mV positive shift in
23
24 the formal potential relative to the solution electrochemistry for **(1)**, possibly due to an
25
26 electrostatic influence of the positively charged polypyrrole chain (Ochmanska 1989).
27
28
29
30
31

32
33
34 Almost symmetrical oxidation and reduction waves for the polymer integrated Fe centers
35
36 were obtained, indicative of the surface bound species. The peak current for an ideally
37
38 responding surface confined reactant is given by equation (1)
39

$$I_p = \frac{n^2 F^2}{4RT} \nu A \Gamma \quad (1)$$

40
41
42 Where n is the number of electrons transferred, F is Faradays constant, ν is the scan rate,
43
44 R is the gas constant, T is the absolute temperature, A is the area of the electrode and Γ is
45
46 the surface coverage or concentration of the redox active adsorbate in mol cm⁻² (Rusling
47
48 2003). **Figure 2(c)** shows the effect of scan rate on the redox system of a co-polymer film
49
50 of **(1)** formed from 5mM **(1)** and 5 mM pyrrole over the range 1- 1000 mV s⁻¹. Well-
51
52 defined oxidation and reduction waves were exhibited at low scan rates with linear
53
54
55
56
57
58
59
60

1
2
3 increases in both anodic and cathodic currents current observed ($1 - 200 \text{ mV s}^{-1}$)
4
5 indicating surface confined behavior. Plots of peak currents vs. scan rate are shown in
6
7
8 **Figure 3(a)** and similar anodic and cathodic slopes indicate that insertion and ejection of
9
10 anions (PF_6^-) during oxidation and reduction occurred at the same speed. At higher scan
11
12 rates, $50 - 200 \text{ mV s}^{-1}$, an increase in ΔE_p was observed, indicating that the process of
13
14 insertion and expulsion of anions in and out of the polymer films was rate limiting at this
15
16 time scale. These plots were produced from different ratios of (1):pyrrole [(1 - 5) : 5]
17
18 using 1 cycle of co-polymerisation.
19
20
21
22
23

24
25 At higher scan rates the layer was no longer exhaustively oxidised, the rate of charge
26
27 transport through the layer influences the voltammetric response and semi-infinite linear
28
29 diffusion controls the peak current (Rusling 2003) (peak current now increases with $v^{1/2}$).
30
31 The effective diffusion coefficient D_{CT} corresponding to 'diffusion' of either electrons or
32
33 charge compensating counterions, can be estimated from the well known Randles Sevcik
34
35 equation (2).
36
37
38
39
40
41

$$i = (2.69 \times 10^5) n^{3/2} A D_{CT}^{1/2} C v^{1/2} \quad (2)$$

42
43
44
45
46 Where C is the concentration of electroactive sites within the film. Slow scan rates
47
48 establish a finite diffusion regime i.e. changes in potential occur at such a time scale that
49
50 the whole layer experiences the effect, whereas in the non-ideal case, films are thick
51
52 (finite diffusion does not occur over the whole film) or there is slow heterogeneous
53
54 kinetics. Many such systems exhibit behavior that is intermediate between 2 limiting
55
56
57
58
59
60

1
2
3 cases finite and semi-infinite (rate limiting charge transfer through film) (Rusling 2003).
4
5
6 The slope of the linear portion of the i_p vs. $v^{1/2}$ plots (data not shown) for films formed
7
8 from 1 cycle growth (1-5 mM ferrocene derivative (**1**) and 5 mM pyrrole) enabled
9
10 estimation of the product $D_{CT}^{1/2} C$ (as film thickness was unknown it was not possible to
11
12 calculate the concentration of sites within the film (C)). The cathodic $D_{CT}^{1/2} C >$ anodic
13
14 $D_{CT}^{1/2} C$ in all cases indicating that anion (PF_6^-) ejection was facile relative to anion
15
16 insertion into the film for charge compensation during redox switching of the Fe^{II/III}
17
18 couple. Values for $D_{CT}^{1/2} C$ decreased from $2.3 \times 10^{-9} \text{ cm}^{-1} \text{ s}^{-1} \text{ mol}$ (5:5) to $1.52 \times 10^{-9} \text{ cm}^{-1} \text{ s}^{-1}$
19
20 mol (2.5:5) to $1.05 \times 10^{-9} \text{ cm}^{-1} \text{ s}^{-1} \text{ mol}$ (1:5) as expected reflecting the decreased redox
21
22 active concentration (C) within the film.
23
24
25
26
27
28

29 **Table 1** presents the average electrochemical data set from multiple scan cyclic
30
31 voltammetric studies on three sets of polymer films formed from different ratio of Fc (**1**)
32
33 and pyrrole, co-polymerised at 100 mV s^{-1} using 1 cycle. The surface coverage (Γ) can
34
35 be determined by measuring the Faradaic charge (Q) passed during exhaustive
36
37 electrolysis e.g. using slow scan rate voltammetry, and values were observed to increase
38
39 with the ratio of Fc derivative (**1**) used in the growth solution, as expected (from 0.88-
40
41 $1.81 \times 10^{-8} \text{ mol cm}^{-2}$). The stability of the films upon cycling (following growth) was
42
43 expressed as % decrease in electroactivity for both anodic and cathodic peaks $i_{p(a)}$ and
44
45 $i_{p(c)}$. The low <10% values obtained in the case of all films examined, was indicative of
46
47 the stable and adherent nature of the films formed under these conditions.
48
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3 For an ideal Nernstian reaction under Langmuir isotherm conditions, $E_{pa} = E_{pc}$ or $\Delta E = 0$
4 (Rusling 2003). Due to the polymeric nature of the films, such ideal behavior was not
5
6 observed and ΔE values increased with increasing scan rate. It was also observed that the
7
8 ΔE values increased with increasing concentration of ferrocene derivative (**1**). Overall,
9
10 this may reflect a limitation due to anion movement into and out of the polymer during
11
12 redox switching, together with decrease of charge transport properties in the films. This
13
14 was less evident in the thinner film formed from 1 mM (**1**) indicating relatively rapid
15
16 electron transfer.
17
18
19
20
21
22
23
24

25 At low scan rates films exhibited a linear ($r^2=0.985$) dependence of $\log(\text{peak current})$ vs.
26
27 $\log(\text{scan rate})$ for both oxidation and reduction currents (data not shown), with slopes in
28
29 the range 0.81-0.84 for films formed 1-5 mM (**1**) with 5 mM pyrrole. Co-polymer films
30
31 formed from 1mM (**1**) and 0.1-1 mM pyrrole resulted in slope values close to 1 (0.91-
32
33 0.97) for all films. Both sets of data indicated Nernstian equilibrium (Ochmanska 1989)
34
35 while a decreased in slope to 0.5 would indicate that the Fe electrochemistry is diffusion
36
37 limited or may be due to ionic resistance of the film i.e. the peak current is limited by the
38
39 rate of counter-ion migration into or out of the film. The relatively lower values for the
40
41 thicker films formed from 1-5mM (**1**) suggests some degree of kinetic limitation.
42
43
44
45
46
47
48

49 For an ideal Nernstian reaction where the redox centers do not interact laterally a surface
50
51 confined species will follow the relationships $E_{pa} = E_{pc}$ and (Rusling 2003).
52
53
54
55

$$FWHM = 3.53 \frac{RT}{nF} = \frac{90.6}{n} mV \quad (3)$$

1
2
3 The full width at half peak maximum (FWHM) values of the films (data shown in **Table**
4 **1**) obtained were higher than the ideal value in particular in the case of the films formed
5
6 from 2.5 and 5 mM **(1)**. No significant difference was observed in the $FWHM_{ox}$ and
7
8 $FWHM_{red}$ values of the films formed from 2.5:5 and 5:5 mM films. This indicated that
9
10 oxidation and reduction of the polymer films was almost equally facile.
11
12
13

14
15
16
17 According to Laviron 1979, for a surface-confined electroactive species with a small
18
19 enough concentration, the charge transfer coefficient (α) and the charge transfer rate
20
21 constant (k_s) for electron transfer between the surface confined layer and the electrode
22
23 can be obtained. A plot of $E_p = f(\log v)$ (**Figure 4**) yields the typical curves with two
24
25 straight lines with slopes equal to $-2.3RT/\alpha nF$ and $2.3RT/(1-\alpha)nF$ for cathodic and
26
27 anodic peaks, respectively. Transfer coefficient (α) values of 0.5, 0.59 and 0.52 were
28
29 obtained for films formed using **(1)**:pyrrole ratios 5:5, 2.5:5 and 1:5 respectively with k_s
30
31 values of 0.11, 0.21 and 0.58 s^{-1} .
32
33
34
35
36
37
38

39 The effect of the concentration of pyrrole on the co-polymerisation of (6-(4-(1H-pyrrol-1-
40
41 yl)phenoxy)hexyl)ferrocene was also examined. As no film formation took place at
42
43 concentrations of pyrrole $<0.1\text{ mM}$, this study examined films formed using pyrrole
44
45 concentration over the range $0.1\text{ -}1\text{ mM}$. **Table 2** presents the average results from cyclic
46
47 voltammetric studies on three sets of co-polymer films formed from different ratios of **(1)**
48
49 and pyrrole, co-polymerised at 0.1 mV s^{-1} over 2 cycles and **Figure 3(b)** shows the i_p vs.
50
51 v plots which were linear up to 200 mV s^{-1} . Surface coverage values for these films were
52
53 lower relative to those in **Table 1**, ranged from $2.2\text{ -}8.5 \times 10^{-9}\text{ mol cm}^{-2}$ and increased with
54
55
56
57
58
59
60

1
2
3 increasing pyrrole concentration, indicating the incorporation of more of the redox
4 species (**1**).
5
6
7
8
9

10 With respect to film stability the $i_{p(a)}$ and $i_{p(c)}$ loss (%) for the co-polymer films of ratio 1
11 : 0.5 were between 1.3-6.3%, and were relatively more stable than the thicker films
12 shown in Table 1. FWHM values were close to ideal for the 1:0.1 mM film as were ΔE_p
13 values and there was less dependence of both ΔE_p and $E_{1/2}$ on scan rate in particular in
14 the case of the thinner films, indicating more ideal reversible behavior and faster electron
15 transfer. Laviron data analysis (plot not shown) resulted in charge transfer co-efficient of
16 0.72 for the cathodic process with $k_s = 0.57 \text{ s}^{-1}$. The linear region of i_p vs $v^{1/2}$ enabled
17 $D_{CT}^{1/2} C$ vales to be obtained with cathodic $D_{CT}^{1/2} C >$ anodic $D_{CT}^{1/2} C$ as before. Average
18 values decreased from 1.6×10^{-8} to $7.13 \times 10^{-9} \text{ cm}^{-1} \text{ s}^{-1} \text{ mol}$ as pyrrole concentrations in the
19 growth solution varied from 0.1-1mM with constant concentration (**1**) (1 mM). This
20 could possibly reflect a decreasing C term (as indicated by the trend in surface coverage
21 shown above) or may reflect more rapid charge transfer for the film formed from 1 mM
22 (**1**):1 mM pyrrole.

43 **Effects of reduction switching potential on the electrical conductivity of (6-(4-(1H- 44 pyrrol-1-yl)phenoxy) hexyl)ferrocene co-polymer films**

45

46 The electrical conductivity of polypyrrole is known to be a function of its oxidation state
47 and hence of the applied potential. The oxidised polymer is highly conductive and the
48 reduced form is semi-conductive or nearly insulating. Over the range 0 - 0.4 V vs. Ag/
49 Ag^+ , conductivity of polypyrrole is constant. At more negative potentials, conductivity
50
51
52
53
54
55
56
57
58
59
60

1
2
3 becomes potential dependent and can drop by up to six orders of magnitude. The
4 stability of the Fe^{II/III} redox couple upon increasingly negative switching (reduction)
5 potential (-1.2-0.2V) was examined (Figure 4) up to the positive limit 0.4 V vs. Ag/Ag⁺.
6
7
8
9
10 It was observed that the polymeric backbone signal was regenerated upon switching from
11 insulating to conducting state but the redox Fe^{II/III} couple started to diminish (in
12 particular the cathodic wave) when the negative potential was extended beyond -0.6 V.

20 **Co-polymerisation of (6-(4-(1H-pyrrol-1-yl)phenoxy) hexyl)ferrocene and pyrrole** 21 **using chronocoulometry**

22
23
24 Chronocoulometry is an alternative method to potential cycling for conducting polymer
25 film formation. This technique involves measurement of the charge vs. time response to
26 an applied potential step waveform. The technique is useful for measuring adsorption of
27 electroactive species, and the mechanisms and rate constants for chemical reactions
28 coupled to electron transfer reactions (Bard 2001). The process was commenced at a
29 potential (Initial E = 0 V) at which there was no electrolysis and then changed
30 instantaneously (stepped) to a value that leads to oxidation or reduction of the species in
31 solution (0.65 V in this case) and was held at that potential for a user-defined time period.

3 **Electrochemical characterisation of co-polymer films formed from ((4-(1H-pyrrol-1-**
4 **yl)phenoxy)carbonyl)ferrocene (1) and pyrrole**
5
6

7
8 Co-polymerisation of ((4-(1H-pyrrol-1-yl)phenoxy)carbonyl)ferrocene (2) and pyrrole
9
10 was performed using potential cycling. Optimisation of growth conditions was
11
12 performed as before, by variation of both (2) (1-5mM) with constant pyrrole
13
14 concentration (5mM) and fixed concentration of (2) (1 mM) with 0.5-1 mM pyrrole.
15
16 These studies were carried out using a fixed number of growth cycles (optimum was
17
18 found to be 2 cycles).
19
20
21

22
23
24 **Figure 6 (a)** shows the film deposition of ((4-(1H-pyrrol-1-yl)phenoxy)carbonyl)
25
26 ferrocene (1 mM) and pyrrole (0.5 mM) over 2 cycles with E^0 for the Fe (II/III) redox
27
28 couple at 0.37 V vs. Ag/Ag⁺. As before, the pyrrole monomer oxidation wave was
29
30 evident at 0.9 V vs. Ag/Ag⁺ and increased currents upon cycling indicates deposition of
31
32 the redox species onto the electrode surface. **Figure 6(b)** shows the cyclic voltammogram
33
34 of the co-polymer films, following polymer growth, being stabilised in a fresh solution of
35
36 0.1M TBAPF₆/ACN over the range +0.2 V to 0.7 V at 25 mV s⁻¹ for 25 cycles. E^0 for the
37
38 film Fe (II/III) couple was 0.447 V vs. Ag/Ag⁺ with a positive shift of **80 mV** relative to
39
40 the solution electrochemistry.

55
56
57
58
59
60

1
2
3 cathodic and anodic peaks over the range 1 - 200 mV s⁻¹, were observed (first 5 cycles are
4 shown here), following which films exhibited semi-infinite diffusion behaviour.
5
6
7
8
9

10 **Table 3 and 4** present the average results from three sets of co-polymer films formed
11 from different ratios of **(2)** and pyrrole, co-polymerised at 100 mV s⁻¹ for 2 cycles. With
12 respect to **Table 3** data the surface coverage (Γ) values were observed to increase with the
13 ratio of Fc derivative **(2)** ($4.9\text{-}6.7 \times 10^{-9}$ mol cm⁻²) as expected. FWHM values, on
14 average, were similar to films formed from **(1)**. E⁰ was stable with respect to scan rate
15 over the range 0-200 mV s⁻¹ with an increase in ΔE as scan rate increased suggesting a
16 kinetic limitation as before. Films showed excellent stability upon cycling with %
17 decrease in electroactivity <6.7% under these conditions. The linear region of i_p vs $v^{1/2}$
18 enabled $D_{CT}^{1/2} C$ values to be obtained with cathodic $D_{CT}^{1/2} C >$ anodic $D_{CT}^{1/2} C$ as for **(1)**.
19
20 Films grown from 5 mM **(2)**: 5 mM pyrrole resulted in an average $D_{CT}^{1/2} C$ value of 2.4
21 $\times 10^{-9}$ cm⁻¹ s⁻¹ mol, 2.25×10^{-9} cm⁻¹ s⁻¹ mol (2.5:5 mM) and 3.3×10^{-9} cm⁻¹ s⁻¹ mol (1:5)
22 with no trend evident with increasing concentration of **(2)** in the growth solution. Slopes
23 of log I_p vs. log v plots for all films grown under these conditions were in the range 0.88-
24 0.99 (very close to the ideal value of 1 indicating Nernstian equilibrium).

15 16 17 18 **Effects of reduction switching potential on the electrical conductivity of ((4-(1H- 19 20 pyrrol-1-yl)phenoxy)carbonyl)ferrocene (**1**) co-polymer films.**

21
22 **Figure 7(b)** shows the stability of the redox couple upon increasingly negative switching
23
24 (reduction) potential (-1.2-0.2V) up to the positive limit 0.7 V vs. Ag/Ag⁺. The redox
25
26 signal for Fe^{III/II} decreased upon cycling with increasingly negative cathodic switching
27
28 potential, but retention of the background signal and the typical polypyrrole features (-
29
30 0.3-0V vs. Ag/Ag⁺) was achieved, indicating regeneration and stability of the
31
32 electroactive conducting polymer film.
33
34
35
36
37
38

39 Chronocoulometry was also employed for ((4-(1H-pyrrol-1-yl)phenoxy) carbonyl)
40
41 errocene/pyrrole film formation, however a very weak redox couple was evident in the
42
43 case of this compound (similar conditions to growth of films from (**1**) were employed)
44
45 and films were not suitable for further evaluation.
46

NH₄PF₆- aqu; 0.1 M LiClO₄- aqu and 0.1 M Tris pH 7.4. Following polymer growth from acetonitrile containing TBAPF₆ or LiClO₄ both co-polymer films displayed poor redox behavior in aqueous medium indicating limited application in aqueous sensing applications as electrocatalysts or redox mediators. A redox couple at E^o = 0.4 V vs. Ag/AgCl was observed for a copolymer film based on (2) examined in Tris buffer pH 6.5 but poor stability prevented any further investigation. Solubility testing of the ferrocene derivatives (1) and (2) was carried out and (2) was slightly more soluble than (1) as the latter has a long alkyl chain which rendered the ferrocene derivative more hydrophobic. Hence polymer growth on (2) was performed in a range of mixtures of acetonitrile and aqueous medium containing LiClO₄. Unfortunately, it was observed that the moderate solubility of (2) in mixtures of acetonitrile and aqueous containing LiClO₄ was not adequate for co-polymerisation to occur.

Conclusion

The successful synthesis and characterisation of new ferrocene derivatives and (6-(4-(1H-pyrrol-1-yl)phenoxy)hexyl) ferrocene (1) and ((4-(1H-pyrrol-1-yl)phenoxy)carbonyl) ferrocene (2) was achieved followed by their immobilisation as redox active films by co-electrodeposition with pyrrole. To our knowledge this is the first such report based on these short and long chain ferrocene derivatives with optimisation of growth conditions and thin film evaluation. Film growth using potential sweeping was found to be most suitable for adherent film formation with well defined redox electrochemistry and surface confined behavior.

1
2
3 These functionalised polypyrrole materials were easy to deposit from non-aqueous
4 electrolytes and have potential applications in electronic or sensor devices.
5
6 Understanding key factors that control electron transfer and charge transport through
7
8 such polymeric films is an important step in their evaluation as functioning sensor
9
10 elements. Such hybrid materials combine the electronic conductivity of conducting
11
12 polymers with the redox properties of metal complexes with the potential to mediate
13
14 electron transfer reactions. A key feature is metal co-ordination directly to the conjugated
15
16 polymer backbone, facilitating electronic interaction between the electroactive metal
17
18 centers and the polymer backbone (Pickup 1999). The materials described here have
19
20 potential electrocatalytic applications in non-aqueous environments, such as
21
22 determination of poorly water soluble pollutants. Additional development could employ
23
24 mixed metal complex co-deposition for electrocatalytic applications requiring multiple
25
26 electronic steps. Further work in our group is focused on the synthesis and deposition of
27
28 new hydrophilic ferrocene pyrrole/thiophene derivatives. The extension of the
29
30 methodology will include electro-entrapment of oxidase enzymes into well characterised
31
32 polymer matrices bearing redox functionalities, and subsequent evaluation of their
33
34 mediating properties.

Figure 1(a)

Cyclic voltammogram of (6-(4-(1H-pyrrol-1-yl)phenoxy) hexyl) ferrocene (1 mM) in 0.1M TBAPF₆-ACN at a glassy carbon working electrode at 10 mV s⁻¹ vs. Ag / Ag⁺ AgNO₃ (10 mM)

Figure 1 (b)

Cyclic voltammogram of ((4-(1H-pyrrol-1-yl)phenoxy) carbonyl) ferrocene (1 mM) in 0.1M TBAPF₆-ACN at a glassy carbon working electrode at 10 mV s⁻¹ vs. Ag / Ag⁺ | AgNO₃ (10 mM)

Figure 2(a)

Co-polymerisation of (6-(4-(1H-pyrrol-1-yl)phenoxy)hexyl)ferrocene (5 mM) + pyrrole (5 mM) in 0.1M TBAPF₆-ACN at 100 mV s⁻¹ over 5 cycles

Figure 2(b) Stability of the 6-(4-(1H-pyrrol-1-yl)phenoxy)hexyl)ferrocene co-polymer formed from 1 cycle in 5 mM (**1**) and 5 mM pyrrole in 0.1M TBAPF₆-ACN at 25 mV s⁻¹ over 25 cycles. Overlaid is background current from a polypyrrole film formed under the same conditions in the absence of (**1**)

Figure 2 (c)

Scan rate study with of for co-polymer formed from 5mM (7) and 5 mM pyrrole in 0.1M TBAPF₆-ACN (1 cycle film – ratio 5:5 mM). Shown are the first 5 cycles.

Figure 3(a) i_p (μA) vs scan rate (mV s^{-1}) for the co-polymer films (6-(4-(1H-pyrrol-1-yl)phenoxy)hexyl)ferrocene in acetonitrile containing 0.1 M TBAPF₆ from 1 cycle of co-polymerisation following stabilisation at 25 mV s^{-1} vs. Ag/Ag⁺ (25 cycles) I and I' = i_{pa} and i_{pc} for Fc : pyrrole 1 : 5; II and II' = Fc : pyrrole 2.5 : 5; III and III' Fc : pyrrole 5 : 5mM.

Figure 3(b)

I_p (μA) vs. scan rate (mV s^{-1}) for the co-polymer films of (6-(4-(1H-pyrrol-1-yl)phenoxy)hexyl)ferrocene in acetonitrile containing 0.1 M TBAPF₆ from 2 cycles of co-polymerisation following stabilisation at 25 mV s^{-1} vs. Ag/Ag⁺ (25 cycles) I and I' = i_{pa} and i_{pc} for ratio of Fc : pyrrole 1 : 1; II and II' = Fc : pyrrole 1 : 0.5; III and III' = Fc : pyrrole 1 : 0.25; IV and IV' = Fc : pyrrole 1 : 0.1

Figure 4(a)

Laviron plot of E_p vs. $\log v$ for co-polymer films of (6-(4-(1H-pyrrol-1-yl)phenoxy)hexyl)ferrocene formed from 5mM (7) and 5 mM pyrrole in 0.1M TBAPF₆-ACN (1 cycle film)

Figure 4(b) Laviron plot of E_p vs. $\log v$ for co-polymer films of (6-(4-(1H-pyrrol-1-yl)phenoxy)hexyl)ferrocene formed from 2.5 mM (7) and 5 mM pyrrole in 0.1M TBAPF₆-CAN (1 cycle film)

Figure 4(c)

Laviron plot of E_p vs. $\log v$ for co-polymer films of (6-(4-(1H-pyrrol-1-yl)phenoxy)hexyl)ferrocene formed from 1.0 mM (7) and 5 mM pyrrole in 0.1M TBAPF₆-CAN (1 cycle film)

Figure 5 (a)

Effect of cathodic switching potential on redox process for co-polymer film of (6-(4-(1H-pyrrol-1-yl)phenoxy) hexyl)ferrocene (1 mM) and pyrrole (0.5 mM) formed from 2 cycles of co-polymerisation, following stabilisation.

Figure 5 (b)

Comparison of three co-polymer films of (6-(4-(1H-pyrrol-1-yl)phenoxy) hexyl)ferrocene (1 mM) + pyrrole (0.5 mM) formed by chronocoulometry in 0.1M TBAPF₆-ACN following cycling at 25 mV s⁻¹ over 25 cycles.

Figure 6(a) Co-polymerisation of ((4-(1H-pyrrol-1-yl)phenoxy)carbonyl) ferrocene (1 mM) + pyrrole (0.5 mM) in 0.1 M TBAPF₆-ACN at 100 mV s⁻¹ over 2 cycles

Figure 6(b)

Stability of ((4-(1H-pyrrol-1-yl)phenoxy)carbonyl)ferrocene (1 mM) + pyrrole (0.5 mM) in 0.1M TBAPF₆-ACN at 25 mV s⁻¹ over 25 cycles

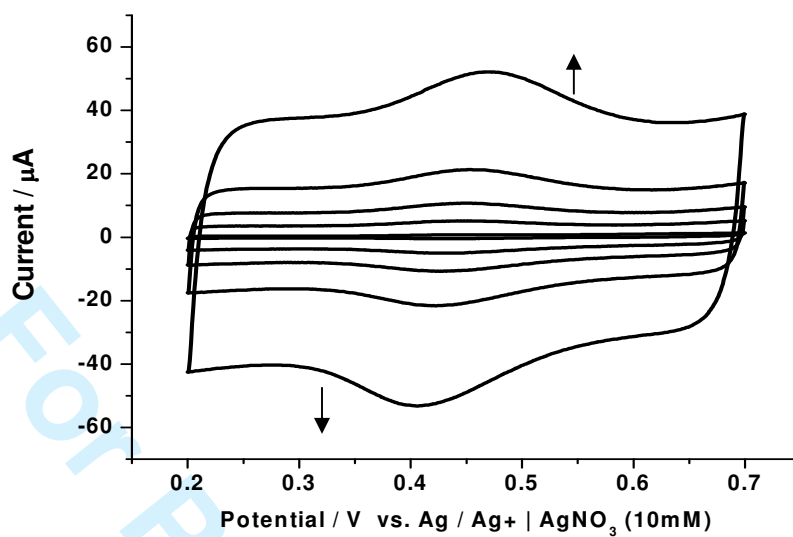

Figure 7(a)

Scan rate study of ($1 - 200 \text{ mV s}^{-1}$) on ((4-(1H-pyrrol-1-yl)phenoxy) carbonyl)ferrocene (1 mM) + pyrrole (0.5 mM) in 0.1M TBAPF₆-CAN

Figure 7(b)

Effect of cathodic switching potential on redox process for co-polymer film of ((4-(1H-pyrrol-1-yl)phenoxy) carbonyl)ferrocene (1 mM) and pyrrole (0.5 mM) over 2 cycles of co-polymerisation, following stabilisation.
