Special Issue on Using Enquiry- and Design-Based Learning to Spur Epistemological and Identity Development of Engineering Students

This Special Issue of the IEEE Transactions on Education focuses on using enquiry-based design projects to spur engineering students’ development, so as to increase understanding and application of the relevant theories, foster higher rates of student development and achieve this in healthy and productive ways.

Each of the eight papers in this Special Issue focuses on a specific aspect, presenting an empirical research study on either epistemological or identity development among engineering students. Five of the papers are on epistemological development or ‘epistemic cognition,’ and three on identity development. The overall set of resources is presented so engineering educators can gain familiarity with existing theories on how students change and grow over their university years, and can consider the findings of empirical studies and what these might imply for their own teaching and for their students’ learning.

I. CALLS FOR CHANGE

“Our house is on fire” argues Greta Thunberg, the 16-year-old environmental activist from Sweden who is successfully shifting public conceptualizations of the natural environment and of climate change where other advocates and scientists had failed to gain traction with the public. Thunberg places the onus on the individual as well as the collective [1]:

“We all have a choice. We can create transformational action that will safeguard the living conditions for future generations. Or we can continue with our business as usual and fail. That is up to you and me.”

In the UK, The Guardian newspaper has taken note. On 17 May 2019, their environmental editor, Damian Carrington, explained [2]:

“The Guardian has updated its style guide to introduce terms that more accurately describe the environmental crises facing the world. Instead of ‘climate change’ the preferred terms are ‘climate emergency, crisis or breakdown’ and ‘global heating’ is favored over ‘global warming,’ although the original terms are not banned.

“We want to ensure that we are being scientifically precise, while also communicating clearly with readers on this very important issue,” said the editor-in-chief, Katharine Viner. “The phrase ‘climate change’, for example, sounds rather passive and gentle when what scientists are talking about is a catastrophe for humanity.”

“Increasingly, climate scientists and organizations from the UN to the Met Office are changing their terminology, and using stronger language to describe the situation we’re in,” she said.”

This example highlights a shift in conceptions of what is needed to solve complex global challenges. This change, from passive observation of a challenge to active participation in its solution, is needed across society, and indeed across engineering. For The Guardian, this represents an alignment of its position as an independent news media organization with the current scientific consensus on the challenge. For engineers, active participation in the solution of global challenges will require conscious awareness of engineers’ role in the broader context of global challenges, and the characteristics of engineering practice that enable meaningful participation [3]. Engineers need to expand the ideas they have about how their work impacts society’s leading “problem solvers.” They are known for being good problem namers, when in fact, they need to become better problem framers. Effective engineering practice in today’s context requires comfort with complexity, and more conscious and deliberate epistemological and identity development.

Global challenges are complex problems, variously described and ill-structured. They are slippery, difficult to identify, and their edges are difficult to ascertain. Solving them requires iterative approaches [4] and the ability to think strategically while continually factoring in new and emerging data to make informed judgements and decisions [5, 6].

The education, and the profession, of engineers can benefit from higher agility, greater comfort with uncertainty, and enhanced skill in complex problem solving [7]. Students must learn that framing and re-framing problems is essential to addressing them more fully. They must learn to handle problems at all scales and align responses at multiple scales.
for greatest affect.

The pressing need for environmental and social justice—in all the many areas that engineers can and do influence—requires an extreme shift away from the status quo. Grand challenges, sustainable development goals, and global responsibility must be prioritized. Engineers must be prepared to change the world and must embrace this challenge and this conceptualization of their role in society.

To do this, engineers need to develop a clear sense of purpose, a clear sense of how professional knowledge is integrated and applied, and a clear understanding of the attributes and abilities unique to engineers of various types. They need to think iteratively and holistically. They need more fluid abilities in design as well as the ability to integrate information, research, analysis at many different scales.

II. THE ROLE OF STUDENT DEVELOPMENT THEORY

To assist students in learning such abilities, engineering education—as a global phenomenon—has embraced active- and enquiry-driven pedagogies, such as problem- and/or project-based learning (PBL and/or PJBL), to various extents. Enquiry-based, hands-on learning was core to engineering since the guilds of the 13th and 14th centuries, but as engineering was being introduced into higher education academies at the start of the 19th century, and the professions were coming to be named and regulated, a shift occurred towards theory and away from practical applications [8]. The earlier, shop-based system challenged students to think in context and see/name/frame problems iteratively in the process of solving them. In universities today, however, engineering students have very few experiences of defining their own engineering problems and continually naming and renaming them as they seek to pin them down and develop effective responses.

Educators must find more ways to expose students to ill-structured problems and design thinking, and help them develop effective practices for making decisions in highly-complex contexts that integrate a wide range of environmental, social and ethical considerations. They must help students develop effective values, attitudes, skills and behaviors—not just textbook knowledge. They must, in fact, prepare their students to generate new knowledge and find new solutions and generate new knowledge. Research shows that students who can restructure their thinking to do this get more out of their higher education and are much better prepared for their careers than those who do not [10].

Most of the approaches that use epistemology as an underlying theory to study university students’ development assume a basic step model, wherein students arrive at college groomed to be receivers of knowledge—knowledge that is generated and validated outside themselves [11], [12]. When entering university, most students are just beginning to grapple with multiple perspectives and with how to resolve incongruent facts and reconcile competing points of view. Such skills are necessary for addressing complex and ill-structured problems, yet the typical engineering student progresses less than two positions along Perry’s nine-position scheme while earning a Bachelor’s degree [13].

Student development theory emerged and expanded from a number of foundational ideas, such as Stanford’s [14] call to balance challenge and support, Astin’s theory on student involvement [15] that describes a positive correlation between learning gains and a student’s level of engagement in rich and productive activities, and Tinto’s well-known theories on persistence-to-graduation [16]. These, combined with typology theories [17], [18], can help individuals identify their strengths, and teams balance their approaches. Identity theories [19], [20], that map the many ways students develop their sense of self and worth, can provide educators with ways of identifying the developmental challenges students face in their journey to become professional engineers.

Although theories on student development are well known among student affairs professionals providing extracurricular and auxiliary support to students, they are less frequently known or applied by academic staff. Understanding these theories may help engineering educators to situate learning for students—helping them to develop incrementally, providing effective scaffolding for their development, and providing an appropriate balance of challenge and support [21].

III. DESIGN THINKING

Transdisciplinary design thinking is core to constructing a sustainable world [22]. Professionals in engineering and related fields cannot continue to produce structures, objects, and responses that fail to consider diverse users,
environmental sustainability, ethics, and social justice. The good news is that design-, project-, and problem-based learning environments can have significant impact on student learning. Such environments can elicit enthusiastic student engagement in solving complex problems. They can involve real-world contexts so that students see relevance—to themselves and society—and connect new experiences to prior knowledge. When thoughtfully applied, design-, project-, and problem-based pedagogies can promote high-level, holistic development among students.

To help educators understand design thinking and support effective learning, Crismond and Adams [23] conducted a comprehensive review of literature in the process of developing a tool that educators can use in teaching design. This tool holds relevance in engineering education, as well as

The move from beginning to informed designer is marked by two key elements: attending to the situated aspects of design (e.g., context, human and social systems, subjectivity), and shifting from approaches appropriate for more well-structured and well-defined problems (means-ends analyses that work well with deductive reasoning problems), to those that are necessary to deal with the uncertainty and ambiguity of ill-structured and ill-defined problems (inductive reasoning problems). In other words, the move from beginning to informed designer is a shift in thinking; an informed designer cannot design by simply using approaches for solving well-defined problems.

Engineering educators are in a position to model effective decision-making—demonstrating for students the process of iterative problem-framing in the process of problem-solving, as discussed in this special issue by Walker et al. In subsequently observing how well students navigate their way through complex problems, they can help students when they encounter difficulty by applying theories and using tools like Crismond and Adams’ matrix.

For educators, learning to model complex thinking and sophisticated forms of cognition for students, and learning to apply development theories while teaching, can be daunting. Engineering educators themselves can benefit from having others to model effective practices. In addition to reading and studying theories on how to promote student development, teachers also need to learn from others on campus who know how to do this. They also need to experience success, in delivering assignments, tutoring students, modeling effective processes and decision-making for students. Teachers can help each other learn how to facilitate students’ ownership of problem-framing, as they work up from small problems to large-scale, complex, and trans-disciplinary problems.

To learn such education-delivery techniques and skills, engineering teachers can band together and take a project-based approach themselves, working together and consulting each other as they incrementally shift the way they facilitate leaning in specific content areas [25]. Co-teaching with others, particularly those with other ways of teaching, framing problems, and conceptualizing the world, can help.

In this special issue, Ozkan et al describe one such scenario, where teachers and students from three significantly different disciplinary perspectives learn together, and begin to identity and reconcile assumptions embedded in their fields that can limit vision by filtering out too much of what they might otherwise see. Disciplinary schemas can be helpful for facilitating quick problem-solving, but being able to understand and tap into ways of thinking and doing within other fields is necessary to holistically addressing problems in today’s world.

IV. AN INTRODUCTION TO THE PAPERS ON IDENTITY

The first set of papers in this issue deals with identity development and the potential of enquiry- and design-based learning to support it. Seminal work in the realm of understanding and describing identity development among third-level students was done by Chickering [26], and further developed and refined by Chickering and Reisser in Education and Identity [27].

Regardless of their specific realm, identity development theories share common elements, wherein the individual moves from: 1) unexamined identity, to 2) conformity, then to 3) resistance and separation, and finally to 4) integration. Identity theories hold relevance for engineering education; they have implications for supporting diversity and helping all students feel a sense of inclusion and belonging. They are also useful for helping student engineers first recognize, and then shape, their professional purpose in society. For a student to identify as a problem-framer, or a person who can solve complex global challenges and improve environmental sustainability and social justice via work as an engineer, could be an important step forward.

In this issue, three papers explore the formation of professional identity, to serve as an introduction to the application of identity theory in engineering education. They look at three specific student populations: (1) early-career electrical and computer engineering students, (2) Latin engineering students, and (3) graduate engineering students.

In “Design Experiences, Identity, and Belonging in Early-Career Electrical and Computer Engineering Students,” authors Jacqueline Rohde, Lisa Musselman, Dina Verdin, Allison Godwin, Brianna Benedict, Adam Kirn, and Geoff Potvin found that design experiences can foster engineering identity and belonging, and that students interpreted these constructs differently. Student descriptions of identifying as engineers centered on how well they performed on authentic engineering tasks and how interesting they found such activities. When explaining their sense of belonging in engineering, students framed the discussion by comparing themselves to peers. The authors aim to help educators foster a healthy sense of identity and belonging among students in engineering and, ultimately, enhance persistence rates.

The paper “Factors Influencing Engineering Identity Development of Latinx Students,” by Meagan Kendall, Maya Denton, Nathan Choe, Luis Procter, and Maura Borrego, reports a mixed-methods study that included an online survey complemented by ten interviews with Latinx students at two different universities in Texas. Three student characteristics predicted 5.9% of the variance in engineering identity; these were attending an HSI, having a parent holding an engineering degree, and gender. Six affective factors explained an additional 28.1% of the variance; these
were engineering interest, engineering recognition, engineering performance/competence, analysis, framing and solving problems, and tinkering. The authors seek to understand student persistence so as to support persistence among Latinx engineers.

Authors Nathan Choe and Maura Borrego focus on engineering graduate students in their paper “Prediction of Engineering Identity in Engineering Graduate Students.” The authors used a multi-scale survey instrument to identify, through factor analysis, four significant and positive predictors of graduate students’ engineering identity: (1) engineering interest, (2) engineering recognition, (3) engineering competence, and (4) interpersonal skill competence. Their final model, created using multiple regression techniques, uses these four factors along with student characteristics; it predicts 60% of the overall variance in engineering identity. The findings are important because this model predicts substantially more than existing models for undergraduate engineering identity. The authors explain that the study “lays the groundwork for future investigations and interventions to foster engineering graduate students’ engineering identities and retention.”

Together, these papers provide guidance on how engineering identity can be examined, and formed through education, to create a more comprehensive picture of students’ path to the profession, and the hurdles and opportunities on that path. The Guest Editors believe that with understanding of how students develop identity, engineering educators can more consciously inform the sense of purpose students develop in university, and help students direct their engineering efforts towards worthy environmental and social causes. These papers on identity help support specific, diverse student groups, and thus promote social justice across the profession of engineering.

V. AN INTRODUCTION TO THE PAPERS ON EPISTEMOLOGY

The second group of papers in this issue focuses on epistemic cognition. Providing an excellent introduction to Perry’s theory as applied to engineering education and research, Jiabin Zhu, Rongrong Liu, Qunqun Liu, and Zhinan Zhang have explored “Engineering Students’ Epistemological Thinking in the Context of Project-Based Learning.” This team built on their prior work developing an instrument, based on William Perry’s schema, to quantitatively assess student development. Interviews were conducted with engineering students to identify demonstrations of students’ relativistic thinking in project-based learning (PBL) activities, and factors connected to students’ relativistic thinking. The researchers identified instances of sophisticated epistemological thinking in students’ descriptions of their broadened thinking, solving problems within constraints, conducting feasibility analyses, integrating commercial considerations, connecting theory with practice, and the like. Epistemological development, the authors assert, was supported by guidance from professors, collaborations with peers, communications with various stakeholders, and dealing with contextually complex and open-ended projects.

Christopher Rennick, Carol Hulls, and Kenneth McKay explored ways to help first-year engineering students move beyond a dualistic worldview, though multiplicity, and into relativism within the specific domain of software design. Their article describes “Introductory Engineering Decision-Making: Guiding First-Year Students to Relativism in Software Design.” They assessed outcome of their intervention using a mixed-methods (survey plus interview) approach using Perry’s framework. The instructors built a semester-long course to teach procedural programming, software design and open-ended, contextualized problem-solving. They implemented coaching methods to help deter students from retreating to the lower positions of the schema as students can tend to do when they feel overwhelmed. “By end of term, most students were comfortable with the concept that there were multiple ways to approach a programming problem and that there were many reasonable solutions, depending on the context and the assumptions made,” indicating that they were approaching Relativism as defined by Perry.

In the context of senior capstone, Erica Walker, Matthew Boyer, and Lisa Benson explored “Using Studio Design to Support Cognitive Apprenticeship and Epistemic Change in the Engineering Classroom.” Data from interviews, video footage of classroom interactions, and written debrief reflections were analyzed thematically. These indicated that cognitive apprenticeship methods applied in a design studio environment had a positive effect on epistemic and cognitive growth for engineering students. The cognitive apprenticeship theory encourages teachers to identify and make explicit, through open dialogue and questioning (by all participants in a classroom) otherwise tacit aspects of the curriculum. This helps counteract the tendency for experts to leave many of their field’s underlying assumptions unstated. These authors explain “The sociological aspects of the Cognitive Apprenticeship framework show that learning, feedback, and reflection should move freely in both directions between instructors and students.” In this study, students developed “epistemic frames including a stronger understanding of themselves and increased confidence in their ability to communicate and approach problems within the context of their chosen profession.”

Jonte Bernhard, Anna-Karin Carstensen, Jacob Davidsen, and Thomas Ryberg also investigated students’ cognitive and epistemological development in advanced design studios. These scholars focused on epistemologies students used in situated action and the students’ development of epistemic fluency. Their paper, “Practical Epistemic Cognition in a Design Project—Engineering Students Developing Epistemic Fluency,” reports qualitative analysis of video of upper-year architecture students working together. The authors’ novel methods integrated ethnographic analysis, conversation analysis, and embodied interaction analysis. Studying ‘epistemologies in action’ these researchers found that students employed models, drawing, diagrams, physical gestures, words, notes, and the like as epistemic tools to build understanding of a design under development. Students also used a wide array of resources to develop shared understanding and produce new design solutions as a team. Advanced design students tended to do this seamlessly, reflecting what the authors call ‘epistemic fluency.’
Like students, educators can also benefit from developing epistemic fluency. The paper “Teacher Learner, Learner Teacher: Parallels and Dissonance in an Interdisciplinary Design Education Minor” by Desen Ozkan, Lisa McNair, and Diana Bairaktarova explains that trans- and interdisciplinary design curricula challenge engineering teachers and students alike. The paper provides a valuable introduction to the Reflective Judgment Model created by King and Kitchener as well as conceptualization of campus learning environments posited by Strange and Banning [28], [29]. The authors drew parallels between the challenges and learning experienced by teaching teams and student teams in one interdisciplinary certificate program, collecting data via interviews, classroom observations, and students’ written reflections in three courses. Like the students enrolled in their modules, the teachers also had to negotiate as they constructed shared understandings of complex contexts. Teachers and students alike addressed disciplinary assumptions and tacit values as they learned to work across fields. Discomfort with uncertainty emerged as a prevalent theme. 

Taken together, these papers point to ways of shifting the perceptions held by students and educators of what engineers do and the responsibilities they bear. Understanding these theories and using them to support classroom activities can help educators support holistic development of students—considering head, heart, hands and health—and foster the abilities that engineering professionals need to design and construct effective and globally responsible solutions to today’s array of needs and challenges.

ACKNOWLEDGMENTS

Thanks go to the many authors, identified above, involved in producing this special focus issue. They have extended this realm of inquiry in engineering education by conducting and reporting their empirical analyses of data collected on three different continents.

Thanks, however, cannot stop there, as dozens of other people supported the work of these authors. The peer reviews and guest editors—representing four different continents—gave countless hours to enhancing the quality and value of the issue. Peer reviewers were: Folashade Akinmolayan, John Bachman, Yifat Ben-David Kolikant, Rebecca Broadbent, Shane Brown, Thomas Cosgrove, Scott Daniel, Inês Direito, Mathew Docherty, Kenneth Faller, Robin Fowler, Kimberly Freeman, Allison Goodwin, Ashley Grifin, Barrett Hazeltine, Sally Male, Robert McQuade, Dan Moore, Stuart Palme, Juliana Pripic, Kenneth Reid, Raul Rengel, Monique Ross, Noah Salzman, Iain Skinner, Jessica Swenson, and Esther Ventura-Medina.

The following guest editors helped Shannon Chance, Associate Editor of IEEE Transactions on Education, guide the character of the overall collection: Bill Williams, Tom Goldfinch, Robin Adams, and Lorraine Fleming. Thanks go to these scholars for persistent contributions of time and effort made over the 18 months while this issue has been under development. Development of this issue was supported financially by the European Union.

The issue also benefits from quality leadership provided by former Editor-in-Chief Jeff Froyd, current Editor-in-Chief John Mitchell, and Editorial Administrator, Kirsty Mills.

REFERENCES

Shannon M. Chance earned her Ph.D. in higher education administration from William and Mary in Williamsburg, Virginia, in 2010, after receiving Bachelor’s and Master’s degrees in architecture from Virginia Tech in Blacksburg, Virginia, in 1993 and 1996 respectively.

She is currently a Visiting Professor and Marie Curie Research Fellow at the UCL Centre for Engineering Education, in London, England and is on career break from her permanent/tenured post as Lecturer in the TU Dublin School of Multidisciplinary Technologies in Dublin, Ireland. She has previously served as a Fulbright Fellow and Marie Curie Research Fellow at TU Dublin, and Full Professor of architecture at Hampton University in Virginia. Her range of publications includes: “Comparing grounded theory and phenomenology as methods to understand lived experience of engineers implementing Problem-Based Learning,” published in the European Journal of Engineering Education; “Using architecture design studio pedagogies to enhance engineering education,” in the International Journal of Engineering Education; and “Strategic by design: Iterative approaches to educational planning,” in Planning for Higher Education.

Bill Williams received the Ph.D. degree in engineering management from Instituto Superior Técnico, Lisbon, Portugal.

He originally trained as a Chemist with University College Cork, Ireland, then worked in education in Ireland, U.K., Eritrea, Kenya, Mozambique, and Portugal, and ran international distance courses for the International Labour Organisation in various African countries.

Dr Williams is currently a vice-president of the Portuguese Society for Engineering Education (SPEE). He is a member of the Centre for Management Studies (CEG-IST), Instituto Superior Técnico, Universidade de Lisboa, is Professor Jubilado of Instituto Politécnico de Setúbal, Portugal and is Adjunct Senior Research Fellow of TU Dublin, Ireland.

Tom Goldfinch earned a B.E. (Mechanical) from the University of Wollongong, Australia, 2006 and a Ph.D. in engineering education from the same institution in 2014.

Tom is currently a Senior Lecturer in Integrated Engineering at the University of Sydney, Australia. Prior to this role, he was a tenured academic specializing in curriculum and assessment design, and academic development at the University of Wollongong, Australia, and worked briefly as a design engineer for Alcatel Australia. Tom’s scholarly work in engineering education has focused on intercultural competence, multidisciplinary learning, professional skills and sociocultural factors in engineering design and practice. His collaborative work on inclusion of Australian Indigenous perspectives in engineering education is his most well recognized work and has influenced directions in this area nationally. Tom has led major government funded projects in these areas and has led or been a major contributor to over AUD 1 million in grants. He has worked on collaborative projects in Australia, Saudi Arabia, UK, and Sri Lanka.

Dr. Goldfinch served as president of the Australasian Association for Engineering Education (AAEE) from 2018-2018. He is also an Associate Editor for the Journal of Engineering Education.
Robin S. Adams holds a Ph.D. in education, leadership and policy from the University of Washington in Seattle (2001), an M.S. in materials science and engineering also from the University of Washington (1996), and a B.S. in mechanical engineering from the California Polytechnic State University at San Luis Obispo. She is currently a Professor in the School for Engineering Education at Purdue University in West Lafayette, Indiana, USA where she is also an affiliate faculty member in the School of Environmental and Ecological Engineering and the Electronic and Time-Based Art program in the Rusty Rueff School of Design, Art, and Performance. She designed and hosted the 10th Design Thinking Research Symposium where researchers from around the globe and different disciplines conducted methodologically diverse studies using a shared dataset of design reviews. This resulted in an edited book, *Analyzing Design Review Conversations* (West Lafayette, IN: Purdue University Press, 2016). Prior to academia she was a Senior Designer for Olin Interconnect Technologies in Santa Clara, CA. Her research is in three interconnected areas: cross-disciplinary thinking; design cognition and learning; and translating educational research to practice.

Dr. Adams is a member of the American Society for Engineering Education, Association for Integrative Studies, Design Research Society, International Network for Engineering Studies, and the Research in Engineering Education Network. Dr. Adams, with her colleagues Alice Pawley and Brent Jesiek, received the Benjamin Dasher Best Paper Award for the IEEE Frontiers in Education Conference in 2012 for the paper “Applying philosophical inquiry: Bringing future engineers education researchers into the philosophy of engineering education.”

Lorraine N. Fleming earned a Ph.D. in civil engineering from the University of California, Berkley following a B.S. in civil engineering from Howard University. She is Professor of civil engineering and Director STEM Education Research Center at Howard University in Washington, DC. She previously served as Interim Dean of the College of Engineering, Architecture and Computer Sciences at Howard University. Her skills and interests include teaching and learning as well as education research. Publications include: “Educating Generation Net—Can U.S. Engineering Woo and Win the Competition for Talent?” in the *Journal of Engineering Education*, and “Stress-Deformation Characteristics of Alaskan Silt” in the *Journal of Geotechnical Engineering*.

Dr. Fleming is a fellow of the American Society of Civil Engineers, a commissioner of the Engineering Accreditation Commission of the Accreditation Board for Engineering and Technology, as well as a member of the American Society for Engineering Education and the national engineering honor society, Tau Beta Pi. During the Obama administration, she received the Presidential Award for Excellence in Science, Mathematics and Engineering Mentoring. The District of Columbia Society of Professional Engineers (DCSPE) named Dr. Fleming its 2014 Engineer of the Year. She serves as the principal investigator and director of the National Science Foundation-funded Global Education, Awareness and Research Undergraduate Program, which provides undergraduate STEM students with opportunities to study abroad as well as gain exposure to engineering research within an international setting.
